↓ Provides 23 programs written for the Hewlett-Packard HP-67/97 programmable calculators. Full documentation is given to clarify the background of topics and to enable the user to program a subject of special interest for a machine other than the HP-67 but with comparable power. Several programs reduce published volumes of tables to one or two magnetic cards. The programs are grouped under the headings of geographic and orbital programs, military models, cost programs, and mathematical functions and algorithms. (WH)

Hand Calculator Programs for Staff Officers

Edwin W. Paxson

Rand
SANTA MONICA, CA. 90406

PREFACE

This report documents and discusses twenty-three programs--written for the Hewlett-Packard HP-67/97 programmable calculators--covering a wide range of problems of interest to staff officers in all the military services. Using this material, the user may quickly obtain answers to specific questions arising in meetings, at the desk, or in the field. Full documentation is given to clarify the background of a topic and to enable the programming of a subject of special interest for a machine other than the HP-67, but with comparable power.

In general, the report avoids the "slide-rule" type of topic where only a given formula is to be evaluated. Rather, topics are chosen that would consume too much of a staff officer's time to program because the underlying mathematics may be obscure, because approximating techniques must be sought, or because the programming itself presents problems.

Several programs reduce published volumes of tables to one magnetic card.

The major part of this research was supported by The Rand Corporation from its own funds.

SUMMARY

The report is summarized by an overview of the topics covered in it.

Part I. Geographic and Orbital Programs

1. Geographic Coordinates to UTM and Conversely

Army tactical maps use Universal Transverse Mercator (UTM) coordinates. For joint operations with the Air Force and the Navy, coordinate conversion to geographic coordinates and the converse is essential. Accuracy of this program is better than 10 meters in the *northing* (distance from the equator) and 1 meter in the *easting* (distance from the central meridian of a zone).

2. Sunrise, Sunset, and Twilight

The times of sunrise and of the various categories of twilight are important in planning many types of military operations and activities, although adverse weather conditions all too often vitiate such planning. This program gives twilight times for any day of the year, at any latitude and longitude, and at any altitude. Accuracy is three minutes or less, except under special conditions such as high latitudes.

3. Geodetic Distances and Bearings

The usual formulas of spherical trigonometry that are programmed to give great circle distances and bearings employ a spherical earth of some mean radius. Distances can be in error by as much as 20 kilometers. The program here uses formulas of the National Geodetic Survey based on Bessel's solution for the geodesic on an ellipsoid of revolution. Accuracy is good, about 0.1" or 3 meters.

4. Reentry Trajectories

The program uses Sec. 20 (Fourth-Order Differential Equations). For a body with zero lift and a given "beta" entering the upper atmosphere, find the subsequent range, altitude, and velocity to impact.

PRECEDING PAGE BLANK

5. Satellite Orbital Elements

This program solves two of many possible orbital problems: Given a satellite's injection altitude, velocity, and flight path angle, find the remaining six orbital elements; or given the injection altitude and the altitudes of perigee and apogee, find the remaining elements. Equations are provided so that other problems may be programmed.

6. Satellite Tracking

Given the time and longitude of equatorial crossing of a satellite, select a ground station. Determine if the orbit can be viewed on that pass, and if so, determine its range, bearing, and elevation from local horizon to horizon as functions of time.

Part II. Military Models

7. The Deer Hunt (Defenseless Bombers)

The model assesses the expected outcome of a time-limited battle in which a group of armament-limited interceptors engages a group of defenseless penetrating bombers. A deer hunt is the paradigm.

8. A Bomber Penetration Model (Defended Bombers)

In this model, the bombers are not defenseless. As part of mission planning, bombers divide their payloads between defense missiles and ground attack munitions to maximize weapons delivered to ground targets.

9. Damage Probabilities, PVN and QVN Targets

The program gives damage probabilities for nuclear weapons of given yield and CEP applied against PVN and QVN targets at the optimal airburst altitude.

10. Four Deuces (Precision 4.2-inch Mortar Fire)

This section is an example of data-table replacement by functional fitting. It applies to the 4.2-inch mortar, reducing firing table corrections and meteorological conditions to formulas. The program yields corrected shell charge and corrected azimuth and elevation for precision fire, and permits a difference in altitude between mortar and target.

11. A Laser Equation

The equation programmed applies to propagation in the atmosphere and allows for blockage, thermal blooming, and jitter factors. Given any two of the three primary variables power, range, and average intensity at the target, the program finds the third factor.

12. Shaking the Dice (A War Gaming Example)

This section provides an example of how random numbers are used in a firefight model to assess outcomes quickly in war gaming. The example employs a conceptual mortar round with an on-board heat-seeker sensor that causes the round to home on an armored target.

13. Optimum Allocation of Resources

The title promises too much. This is a topic in nonlinear, convex programming. Military applications arise in search planning, allocating weapons to target classes, and allocating budgets.

Part III. Cost Programs

14. Log-Linear Cumulative Average and Unit Costing

These programs implement the basic assumption of learning curve theory as it applies to production. That is, each time total production doubles, the cost per item reduces to a constant percentage of the previous cost.

15. Time-Phased Procurement Costing

Consider a system, weapon or otherwise, with several major components. Each component has its own lead time and its own, possibly segmented, learning curve. Specify a delivery schedule over future years, and find the New Obligational Authority by fiscal year to support the program.

16. Cost/Benefit Streams

This model deals with the decision to spend money now as opposed to later during the life cycle of a weapon system. For example, should engineering development money be spent now in the expectation that future operating and support costs will be lower? The yardstick is the present value of a discounted stream of cost and benefits (savings). An "internal rate of return" is calculated to provide go-no-go for the decision.

Part IV. Mathematical Functions and Algorithms

17. The Normal Function and Its Inverse

The normal function (probability integral) is pervasive in military calculations. The program is frequently used in conjunction with others, such as that for the Q function.

18. The Q Function (Offset Coverage Function)

The Q function is used in radar detection theory and offset bombing calculations, as well as in calculations of collateral damage to point targets.

19. Linear Programming and 3×3 Matrix Games

Many models may be stripped in a meaningful and transparent formulation to three activities as a programming problem, or to three own courses of action pitted against an enemy's three courses of action, in order to make a command decision by game theory. This program uses the pivot method and has some interesting indexing aspects.

20. Fourth-Order Differential Equations

This program supports applications to reentry trajectory determination, Lanchester models of combat, and optimal control theory.

21. Curve Families and Mach Numbers

Military data are frequently presented as sets of tables or as families of curves, with a parameter naming the family member. This section suggests methods of representing these data through curve-fitting, using elementary functions. The methods are applied to the determination of best Mach number for the A-7D aircraft on long-range, constant-altitude cruise.

22. Ten-Point Gaussian Integration

This is a utility program for evaluating definite integrals as they arise. Accuracy is usually excellent. For example, incomplete elliptic integrals are computed to eight decimal places by this method.

23. Truth Tables

A calculus of propositions is tailored for ready implementation by the calculator. The program systematically solves problems in

symbolic logic, consisting of a set of logical conditions that the atomistic propositions must satisfy. There are real-world applications, usually overlooked.

ACKNOWLEDGMENTS

H. G. Massey provided the models for the sections on time-phased procurement costing and cost/benefit streams. D. C. Kephart programmed the damage probabilities for PVN and QVN targets, based on his earlier work. Lieutenant Colonel R. S. DeLaney, USAF, brought the laser equation to my attention. I am grateful to these men and also to the technical reviewers, W. B. Graham and R. N. Snow, for their comments. Roger Snow went well beyond a meticulous technical review. He provided a more efficient program for the Q function and prepared several flow-charts to clarify program logic. I am grateful for his collaboration.

Of course, errors found are to be laid to my door.

PRECEDING PAGE BLANK

TO THE USER OF THIS REPORT

If your temperament is like that of the author, this description of the psychology of programming will sound familiar: After the usual time-consuming process of getting the mathematics of a topic in shape, the urge is to program as quickly as possible and make independent checks of the validity of the outputs. It works! And we move on to something else.

Any program, however, certainly including those in this report, can be improved--can be shortened and made more elegant and transparent. The result of this product-improvement effort may be to reduce the running time and to find program and storage space to extend the program's capability. A reexamination of program logic is part of this effort. The program may be made more robust, minimizing operator errors that occur when complex input operations are otherwise required.

If you as a user are interested in a particular topic in this report, you may choose to make this extra effort, which will be repaid with an enriched understanding of hand calculator programming.

Finally, you are invited to communicate to the author any errors you detect, errors and unforeseen restrictions being inevitable in a report of this nature. You are also invited to send to the author, for possible future programming, descriptions of topics that you feel may be of interest to some significant subset of the staff officer community. And by all means, copies of your own programs would be welcomed.

PRECEDING PAGE BLANK

INTRODUCTION

"The general who wins a battle makes many calculations in his temple ere the battle is fought. The general who loses a battle makes but few calculations beforehand."

- Sun Tzū Wu, *The Art of War*, ca. 500 B.C.

Programmable hand calculators are little more than five years old, but they are already in their third generation, the gestation period being one and a half to two years. Up to now, they are unique in our inflationary world, in that each new generation has much more power than its predecessor, but sells for much less. This cost trend may reverse should these calculators become more competitive in power with microprocessors.

We can assess the impact in the civilian sector by noting that the number of user programs submitted to the Hewlett-Packard HP-67 program library is approaching 3000. The PPC (Personal Programmers Club),^{*} with more than 2500 members, is a nonprofit worldwide group of people who own and use PPCs (personal programmable calculators). The monthly club newsletter contains a wealth of programs and imaginative programming techniques.

Remembering that modern digital computers were initiated by the military under the pressures of World War II, it is curious that these PPCs, these powerful little animals, are not as equally widespread in the service of the Department of Defense as in the civilian sector.

The PPCs *are* used, of course. The Joint Technical Coordinating Group for Munitions Effectiveness (JTCC/ME) under the JCS has had 25 HP-67 programs prepared for mission planning by squadron ordnance officers in the Air Force, Navy, and Marine Corps. The Strategic Air Command uses the HP-65 in bombing mission planning. Some System

^{*} 2541 W. Camden Place, Santa Ana, CA 92704; Attn: Richard Nelson.

Project Offices (SPOs), such as the F-16 SPO at Edwards Air Force Base, use the HP-67. Junior officers are using their own funds to purchase PPCs, which in some cases must represent a tradeoff against a new TV set. But there is no recognizable community of users in the military sector. There is no mechanism--no clearinghouses like those in the civilian world--to exchange programs, to share ideas, and to state requirements for new programs. The notion of a loosely organized "national security users group" to achieve these implied objectives naturally comes to mind. We hope that this report may have some catalytic effect in accelerating such a development.

The hand calculator is particularly suited for military use because so many applications can be made in the field or in a meeting where a senior officer wants a quick answer to support a decision, or where a briefer is to be confounded. But for field use the calculator as *currently* designed would probably not meet military specifications. The operating range for the HP-67 is 10° to 40°C (50° to 104°F) and the battery pack life under continuous use is about three hours before recharging or replacement is required. However, current machines are compatible with avionics, producing little or no interference with sensitive electronic circuits.

But powerful as they are in their domain, the PPCs are far from a final answer to personal computing, although this statement depends on their future evolution. In preparing this report, many instances occurred where much more storage than available was needed and where it was frustrating not to have available a programming capability of more lines of code with a higher-level interpretive language.

Again, the civilian sector is leading the way. More than 120 companies are now manufacturing microprocessors with peripherals for home use, and more than 900 home computer dealers in the United States are marketing these machines at relatively modest prices. Memory may be added, there is keyboard input and cathode ray tube display, with BASIC apparently the language of choice. The military is lagging, even though it is a reasonable bet that many staff officers would like to be freed from the computing-center bureaucracy in doing their daily jobs.

But once more, too strong a position should not be taken. Military computing in general requires large main frames to support extremely large data bases and programs with a million or more lines of code. One would certainly hesitate to try to use a microcomputer for logistic management or for solving three-dimensional partial differential equations.

Nevertheless, there is a real gap in the spectrum of required computing capability to meet military requirements, a gap whose filling this report can only adumbrate.

A word of apology is in order. Recorded program cards are not provided with this report. The reasons are:

- No recipient is likely to use all programs;
- The per-copy cost of the report would be high;
- It requires 10 to 20 minutes to key in a program and check it; and
- Hopefully, the keyer will understand the program and be able to modify or tailor it to his or her desires.

It is recommended that users step through the illustrative problems to get the mechanics straight. And it is always a good idea to do a problem twice. Errors in keying are easy to make, especially when under pressure.

Finally, what is to be said to the staff officer who wants to program his or her own problems on a PPC? The natural question for the officer to ask first is: What bounds a problem that can be "fitted" to the machine?

The general answer is: If the problem can be formulated as a *chain* of subproblems, each of which is within the machine's coding and storage capability, then there is in principle no bound. For example, in the prediction of tides by harmonic analysis,^{*} 37 constituents (cosine terms) each with three constants are employed. Since these terms need only be added, one program card and five data cards,

^{*}Special Publication No. 98, U.S. Department of Commerce, 1940.

used successively, would suffice. As other examples, six linear algebraic equations in six unknowns can be solved using both sides of two cards, and a Star Trek battle can be programmed with eight cards.

For problems that can be chained, the practical limitation is execution time, which can be long and hardly acceptable if many problems are to be run, as in tidal prediction.

But not all problems can be chained. Operations with matrices of order higher than five, and solutions of partial differential equations, are usually nonchainable.

Even if a problem *should* fit, it is frequently hard to see how to make it actually conform to the calculator's Procrustean bed. This could be because the underlying mathematics, including approximating techniques, is beyond one's reach. The help of a specialist colleague is then essential. Once this mathematical hurdle is cleared, programming--which is really an art form with personal brush strokes--can be exasperating. Advice? Read and understand good programs, as many as possible--something that few of us have the self-discipline to do.

As a postscript to this Introduction, an as yet unexploited area of the military application of PPCs should be mentioned. Two or more people may operate their calculators in parallel, engaging in a co-operative, interactive exercise.

For example, two submarines may be allies in a simulated battle against one enemy boat. The purpose of the exercise is to examine, by repeated simulation runs, the tactical utility of communications between the two friendly boats during the battle--ranging from none, through restricted, to complete information and command exchanges. Each player has his own program which, by sampling from probability distributions, shows the output of his sensor systems in respect to target position and bearing, and the damage, if any, inflicted by ordnance launched. Each player keeps his own log and battle plot. At each battle increment (say, 15 minutes of real time), the calculators may be physically exchanged so that, as appropriate, information can be entered in assigned storage registers, and the calculators then returned to the right boats.

As another example, a War College seminar may be examining the cost implications over the next ten years or more of various possible strategic postures. Weapon systems may be phased in and out. New systems require research and development monies and time. In general, each weapon system has cost profiles of funds required for RDT&E, procurement, and annual maintenance and operating expenses. The cost envelope of each weapons system with respect to time is calculated by the seminar member assigned that system. All programs are the same, differing only in their cost and time parameters. The seminar leader totals the year-by-year costs of all systems in the posture and checks for feasibility against an assumed yearly ceiling. After discussion, the seminar members revise phasing or numbers procured and go through another iteration to see if the ceiling is reached or exceeded, and to determine if the posture is balanced in regard to the threat and required missions.

These examples have indeed been programmed for interactive computing on large computers; but this is time-consuming and facilities may not be readily available. The suggested use of PPCs in parallel is an option that can be implemented quickly and can provide a shake-down for more sophisticated approaches, which in some cases may prove not to be warranted.

-7-

PART I

GEOGRAPHIC AND ORBITAL PROGRAMS

PRECEDING PAGE BLANK

1. GEOGRAPHIC COORDINATES TO UTM AND CONVERSELY

1.1. REFERENCES

- a. *Universal Transverse Mercator Grid*, AMS Technical Manual No. 19, Army Map Service, Corps of Engineers, Washington, D.C., 1952.
- b. *Map Projections*, P. Richards and R. K. Adler, North-Holland, 1972.
- c. *Map Reading*, FM 21-26, Department of the Army, October 1960.

1.2. DISCUSSION

Tactical-scale (1:50000) Army maps use the Universal Transverse Mercator Grid (see Ref. c). The map borders show latitude and longitude ticks, but it is difficult to locate the geographic coordinates of a point with any precision. Conversely, Air Force maps use geographic coordinates only. Consequently, in joint operations such as targeting, coordinate conversion from one system to the other is essential. FORTRAN programs exist. The program used at The Rand Corporation has 132 lines of code. Although perfectly adapted to the preparation of coordinates for a list of agreed targets, it hardly meets the requirements of ad hoc field use.

The UTM system covers the world between 80°S and 84°N. Starting at the 180° meridian of longitude and moving eastward, the globe is divided in zones 6° of longitude in width, numbered 1 to 60. Each zone has a central meridian (CM). The following formulas relate zone number (ZN) to the CM:

$$ZN = (CM + 183)/6$$

$$CM = (6 \cdot ZN) - 183$$

For example, Fort Knox, Kentucky is about 86°W. Hence the ZN is the rounded value of $(180 - 86)/6$, $ZN = 16$, and $CM = -87$ or 87°W. (See Ref. c for further details on lettering 8° zones south to north, and on double-lettering for 100,000 meter squares within each 6° × 8° block.)

The value assigned to the CM in each zone is 500,000 meters, called the *false easting*. Hence locations in a zone west of the CM have an *easting* less than 500,000 and conversely. The *northing* is the distance from the equator in meters. For the Southern Hemisphere, the equator is assigned a *false northing* of 10,000,000 meters and numbers decrease southward.

The major complication in coordinate conversion is that allowance must be made for the earth's oblateness. Hence the equatorial radius a and the polar radius b must be selected. Actually, a and the reciprocal of the flattening $f = (a - b)/a$ are given. For the International Spheroid,

$$a = 6\,378\,388 \text{ m}, \quad 1/f = 297.$$

Since $f = 1 - \sqrt{1 - \epsilon^2}$, where ϵ is the eccentricity,

$$\epsilon^2 = 0.006\,722\,67.$$

Unfortunately, different spheroids (different a and f) are used for different areas of the world, for historical reasons. For example, the Clarke 1866 spheroid is used for North America. The other spheroids used are Clarke 1880, Everest, and Bessel. The International Spheroid is used for Europe. (Consult Ref. a.) Consequently, the data a , ϵ^2 , $n = (a - b)/(a + b)$ used here have to be changed for certain parts of the world.

1.3. EQUATIONS

The full equations for the conversions (Refs. a and b) are quite lengthy because extreme accuracy is desired in surveying applications. For military purposes, it is possible to dock the tails of these formulas and still get accuracies better than 1 meter in the *eastings* (E') and better than 10 meters in the *northings* (N)--the distance from the equator in meters.

1.3.1. Geographic Coordinates to UTM Grid Coordinates

$$N = (I) + (II)p^2 + (III)p^4 \quad (1)$$

$$E' = (IV)p + (V)p^3 \geq 0, E = 500\,000 \pm E' . \quad (2)$$

South of the equator,

$$\bar{N} = 10\,000\,000 - N . \quad (3)$$

The given coordinates are latitude ϕ and longitude λ . Then $p = 0.0001 \cdot \Delta\lambda$, where $\Delta\lambda$ is the difference of longitude from the CM, measured in seconds. E' is the (positive) distance from the CM.

$$(I) = S \cdot k_0, \text{ where} \quad (4)$$

$$S = A \phi - B \sin 2 \phi + C \sin 4 \phi .$$

S is the true meridional distance from the equator in meters and

$$A = a[1 - n + 0.75 n^2(1 - n)]$$

$$B = 1.5 a n(1 - n)$$

$$C = 0.9375 a n^2(1 - n), n = (a - b)/(a + b)$$

$k_0 = 0.9996$, the central scale factor to reduce distortion.

$$(II) = \frac{k_0 \sin^2 1'' \cdot 10^8}{4} \cdot v \sin 2 \phi, \text{ where} \quad (5)$$

$v = a / \sqrt{1 - \epsilon^2 \sin^2 \phi}$ is the radius of curvature in the prime vertical.

$$(III) = \frac{k_0 \sin^4 1'' \cdot 10^{16}}{24} \cdot v \sin \phi \cos^3 \phi (5 - \tan^2 \phi) \quad (6)$$

$$(IV) = k_0 \sin 1'' \cdot 10^4 \cdot v \cos \phi \quad (7)$$

$$(V) = \frac{k_0 \sin^3 1'' \cdot 10^{12}}{6} \cdot v \cos \phi (2 \cos^2 \phi - 1) \quad (8)$$

1.3.2. UTM Grid Coordinates to Geographic Coordinates

$$\phi = \phi' - [(VII) q^2 - (VIII) q^4]/3600 \quad (9)$$

$$\Delta\lambda = [(IX) q - (X) q^3]/3600 \quad (10)$$

$$q = E' \cdot 10^{-6} \geq 0$$

$$\phi'' = N/Ak_0 \quad (11)$$

$$\phi' = \frac{N/k_0 + B \sin 2 \phi'' - C \sin 4 \phi''}{A} \quad (12)$$

$$v = a/\sqrt{1 - \varepsilon^2 \sin^2 \phi''} \quad (13)$$

$$(VII) = \frac{10^{12}}{2k_0^2 \sin 1''} \cdot \frac{\tan \phi'}{v^2} \quad (14)$$

$$(VIII) = \frac{10^{24}}{24k_0^4 \sin 1''} \cdot \frac{\tan \phi' (5 + 3 \tan^2 \phi')}{v^4} \quad (15)$$

$$(IX) = \frac{10^6}{k_0 \sin 1''} \cdot \frac{1}{v \cos \phi'} \quad (16)$$

$$(X) = \frac{10^{18}}{6k_0^3 \sin 1''} \cdot \frac{1 + 2 \tan^2 \phi'}{v^3 \cos \phi'} \quad (17)$$

1.3.3. Data Card (International Spheroid)

| 500 000 | STO 6 |

2.4. PROGRAM NOTES

- It will be noted that the powers of 10 in the program differ from those in the formulas because $10^6 \sin 1''$ is a stored datum.
- West longitude is prefixed by a minus sign.

Example 1. N 49°48'00", E 08°24'0" to UTM.

49.48 STO D, 8.24 STO E, 9 STO 7 (CM)

Press A: Northing = 5516670 (5516677.7)

Press R/S: Easting = 456820 (456819.7)

The numbers in parentheses are the AMS values.

Example 2. Northing = 5516677.7, Easting = 456819.7 to geographic coordinates.

N STO D, E STO E, 9 STO 7

Press A: Latitude = 49.4801 (49°48'01")

Press R/S: Longitude = 8.2360 (8°24'00")

2. SUNRISE, SUNSET, AND TWILIGHT

2.1. REFERENCES

2.2. DISCUSSION

Charts are prepared and issued for each major military operation or operational area giving sunlight, moonlight, and tidal data. Nautical twilight (sun's zenith angle from 102° to 96°) provides enough illumination for most types of ground activity, although bomb loading and repair work require artificial light. Civil twilight (sun's zenith angle from 96° to 90°) permits normal day activities such as observed artillery fire and visual bombing. Sunrise occurs when the sun's upper limb has a zenith angle of 90° . This makes the zenith distance of the sun's center $90^\circ 50'$ (90.83°), allowing $34'$ for horizontal refraction and $16'$ for the sun's semidiameter. For some aircraft applications, a correction of $1'.17\sqrt{h}$ is added, where h is the altitude in feet. If H is in kilofeet and decimal degrees are used, this correction is $0.617\sqrt{H}$ degrees.

2.3. EQUATIONS

The fundamental relation (Ref. c, p. 403) is

$$\cos h = -\tan \phi \tan \delta + \sec \phi \sec \delta \cos z, \quad (1)$$

where h and δ are the hour angle and declination of the sun at the time of the phenomenon, ϕ is the latitude, and z is the zenith angle. (The correction of the declination from ephemeris noon to approximate rising or setting is at most 0.1° , a refinement we will neglect.)

The sun's declination is the number of degrees the earth's axis departs from a plane that is normal to the sun's direct rays. The declination is tabulated in the annual Ephemeris. An approximate formula is derived and checked against the tables.

In Fig. 2.1, θ is the true anomaly on day \bar{D} and α is the eccentric anomaly.

Fig. 2.1—Anomalies

Kepler's equation is

$$\alpha - \epsilon \sin \alpha = \frac{2\pi \bar{D}}{365}, \quad (2)$$

where $\epsilon \doteq 1/60$ is the eccentricity of the earth's orbit. Also,

$$\sin \alpha = \frac{\sqrt{1 - \epsilon^2} \sin \theta}{1 + \epsilon \cos \theta}. \quad (3)$$

Neglecting $\sqrt{1 - \epsilon^2}$ ($= 0.99986$), and solving for θ yields

$$\sin \theta = \frac{\sin \alpha}{1 \pm \epsilon \cos \alpha}, \quad (4)$$

where the + branch is used from the vernal equinox, 21 March (Day 89), to the autumnal equinox, 23 September (Day 275).

From (2) a first approximation to α is simply $\alpha_0 = 2\pi D/365$. This is refined by using $\alpha = \alpha_0 + \Delta$ in (2) to get the correction

$$\Delta = \frac{\sin \alpha_0}{60 - \cos \alpha_0} \text{ (radians)}. \quad (5)$$

Finally, using direction cosines, the declination becomes

$$\sin \delta = -\cos \theta \sin \nu, \quad (6)$$

where $\nu = 23.44^\circ$ is the inclination of the earth's axis. The sign becomes + between the two equinoxes as the earth passes through the summer solstice, 21 June.

Next a formula for the Equation of Time (EOT) is required. The EOT is the difference in hour angle of the sun and the fictitious mean sun used for ordinary time. The difference owes to two causes: (1) the variable motion of the sun because of the eccentricity of the earth's orbit, and (2) the obliquity of the ecliptic.

The figure on p. 147 of Ref. a suggests that

$$\text{EOT} = -A \sin (\theta - a) - B \sin (2\theta + b). \quad (7)$$

We get from that figure the approximate values $A = 8$, $a = 5.92^\circ$, $B = 10$, $b = 4.73^\circ$. Here Day 0 ($D = 0$) is 25 December, since the EOT is 0 on that date.

The extrema of the EOT are:

| | | |
|-------------|---------|--------------------|
| 12 February | D = 49 | EOT = -14.29 min |
| 14 May | D = 140 | EOT = +3.72 min |
| 26 July | D = 213 | EOT = -6.46 min |
| 3 November | D = 313 | EOT = +16.41 min . |

Replace A by $A + \Delta A$, etc., substitute in (7), take only first-order terms, and get four linear equations in the unknowns ΔA , Δa , ΔB , Δb . These are solved quickly by Program 7 of the Hewlett-Packard Math Pac 1. The corrected values of the parameters are

$$A = 7.4447, \quad a = 5.935, \quad B = 9.894, \quad b = 4.941.$$

The resulting mean absolute error throughout the year with respect to the tabulated values of the EOT is 24 sec.

Rising and setting times are now computed by

$$\begin{aligned} \text{Rising} &= 12 - \text{EOT} - h \\ \text{Setting} &= \text{Rising} + 2h. \end{aligned} \tag{8}$$

These are local mean times with respect to the central meridian (CM) of a given time zone. To correct for other longitudes, subtract 4 min for each degree east of the CM, since the sun is earlier, and add 4 min for each degree west of the CM. The correction is programmed.

2.4. PROGRAM NOTES

(1) The day number D ($\bar{D} = D + 3$) for a given date is needed, counting from Christmas as Day 0. Subtract 1 from the month number and multiply by 30.42, the average number of days in a month. Take the integral part. For month numbers 1, 8, 9, 10, 11, 12, add 6; for months 3, 4, 5, 6, 7, add 5; and for month 2, add 7. Finish by adding the days of the date.

(2) For the longitude correction (f LBL 0) add 360° if West longitude (entered negative). Then obtain the correct central meridian by checking whether the fractional part of the longitude divided by 15 is less than or greater than 0.5 (1/2 hr).

(3) At dates when the sun's declination is close to 0, formula (4) can yield a number very slightly greater in absolute value than 1. This would generate an Error signal. Such a number is replaced by 1 in f LBL 5.

(4) This program required 220 steps. There was not space to program rising and setting in the Southern Hemisphere. To do this, proceed as follows:

- Find the sun's declination on the desired date.
- Change the sign and use formula (6) to get a new θ and a new day number ($365 \cdot \theta/360$), differing by about 6 months.
- Find the rising time for the latter day in the Northern Hemisphere.
- Add $EOT_2 - EOT_1$.

Example. Find sunrise on 5 May at 38°S (Central Meridian). Run program with $+38^\circ$. RCL 2 to get $\delta = 15.48^\circ$ (the true declination is 16.15°). RCL 1 to get $EOT_1 = .0600$ hr. By (6) with $\delta = -15.48$, $\theta = 47.9$ or 312.1 . Choose the latter. $D = 317$, or 7 November. Run program with date 11.07. Rising time is 6 h 32 m (6.53), $EOT_2 = 0.26$. Rising time is $6.53 + 0.26 - 0.06 = 6.73$ or 6 h 43 m. The value for this example given on p. 566 of Ref. (b) is 6 h 45 m.

(5) Program running time is about 25 sec. Compared with the values tabulated in Ref. b (pp. 434ff), errors are 0 to 3 min with 0 and 1 the most likely values. The errors can be greater, however, at high latitudes at dates close to those with twilight lasting all night.

Example. Astronomical twilight, 50°N , 14 July: The computed value is 0 h 31 m versus the actual 0 32 for beginning, and 23 39 versus 23 32 for end of twilight.

3. GEODETIC DISTANCES AND BEARINGS

3.1. REFERENCES

- a. Erwin Schmid, *Triangulation Position Computation Without Tabulations*, unpublished Ms., National Geodetic Survey, July 1972.
- b. P. A. Smith and H. G. Massey, *A JOSS Program for the Geodetic Inverse Computation*, The Rand Corporation, P-4950, January 1973.

3.2. DISCUSSION

The programs usually written for great circle distances and bearings assume a spherical earth of some mean radius and employ the elementary formulas of spherical trigonometry. The results can be in error by as much as 20 kilometers. To the geodesist (which I am not), such programs are to be anathematized. But beyond the evident demands of surveying, there are applications in the military and international domains where much greater precision is required.

In 1828, F. W. Bessel gave the general solution for the geodesic on an ellipsoid of revolution. Two differential equations must be solved as part of Bessel's rigorous procedure.

Unfortunately for rigor, the geodesist's world is neither perfect nor static. Periodically, the semi-major and semi-minor axes of the geoid are changed somewhat in value. We recommend using WGS 72 (World Geodetic System 1972), now rather generally accepted, which assumes

$$a = 6\,378\,135.0 \text{ m} \qquad b = 6\,356\,750.233 \text{ m} ,$$

and hence a squared eccentricity of

$$e^2 = 1 - (b/a)^2 = 0.006\,694\,407 .$$

(The reciprocal of the flattening f is 298.256.)

The *forward* problem in geodesy takes the latitude and longitude of a station, an azimuthal bearing measured clockwise from north, and

a distance or geodetic segment, and asks for the geographical coordinates of the terminus of the segment. The *inverse* problem wants the geodetic distance between two stations, given their geographical coordinates, as well as the bearings of each station from the other.

3.3. EQUATIONS

The equations for the solution of these two problems are rather lengthy. To conserve space in this report, they are not reproduced here. They are found in Ref. b, available from The Rand Corporation, Publications Department, Santa Monica, CA 90406.* For those readers who delve into this reference, note that in the *forward* solution programmed here there is a replacement in formula (8) of

$$\frac{1 - k}{1 + k^2/4} \quad \text{by} \quad 1 - k ,$$

since $k^2/4$ is less than 1×10^{-6} , and there is a deletion in formula (10) of the term

$$\frac{29}{48} k^3 \cdot \cos 6 S' \cdot \sin 3 \Delta S' ,$$

which is of the order 1×10^{-9} .

This is done to save scarce program space and to accelerate execution slightly. In comparing the results with the more exact values found by the National Geodetic Survey, the resulting latitude may be in error up to 0.2" (6 meters), and the longitude by considerably less than this.

3.4. PROGRAM NOTES (FORWARD SOLUTION)

(1) There are three places in the program where care must be taken to ensure that the arctangent gives an angle in the correct quadrant. The ' \tan^{-1} ' function on the HP-67 produces angles only in quadrants I and IV, but the rectangular-to-polar-coordinate conversion provides the correct quadrant for +/+, +/-, -/-, and -/+. Key

* Price to private individuals: \$3.00 postpaid.

in the y value, the numerator with *its* sign. Press ENTER. Key in the x value, the denominator with its sign. Press g → P. Press h x ↔ y to get the angle.

(2) Stack manipulation is used in two places to hold values in stack storage until they can be placed in primary storage, avoiding the extra steps involving 'f P ↔ S' if secondary storage were used. It is good practice in such programming to use 'SST' in run mode and get successive traces of the stack contents by 'g STK'. (This is *pre*-bugging rather than *de*-bugging.)

(3) Because of program size (218 steps), the user is asked to make, if necessary, a simple final correction to the displayed longitude (8 and 9 under 3.5.1, User Instructions). It is important to use '360, CHS, h H.MS+' rather than straightforward subtraction in step 8.

Examples. The following comparisons with National Geodetic Survey values use their geoid constants of

$$a = 6\,378\,145.00 \text{ m} \qquad b = 6\,356\,759.76 \text{ m}$$

$$e^2 = 0.006\,694\,545 \text{ .}$$

Moreover, their *inverse* solutions (geoid distances as segment lengths) are used to check *forward* solutions. (Note: To convert kilometers to nautical miles, divide by 1.852 exactly.)

Let the station of origin be the municipal airport at Fairbanks, Alaska--64°49'08.95", -147°51'51.36". Then we find

| Place | Los Angeles | Jakarta | Tel Aviv |
|------------|----------------|---------------|---------------|
| Azimuth | 135°12'18.42" | 281°25'57.06" | 357°45'26.32" |
| Kilometers | 3961.6444 | -11344.3480 | -9259.2287 |
| Latitude | 34°02'59.93" | -6°10'00.16" | 32°04'59.79" |
| Δ lat | 0.07" | 0.16" | 0.21" |
| Longitude | -118°13'59.96" | 106°49'59.93" | 34°46'0000" |
| Δ long | 0.04" | 0.07" | 0.00" |

If the azimuth (bearing) is greater than 180° , the distance is entered as a minus quantity. The Δ 's show the difference with respect to the NGS's more accurate value (0.10" in latitude is about 10 feet).

3.5. PROGRAM NOTES (INVERSE SOLUTION)

(1) In this program also, the 2-parameter arctangent procedure must be followed to get angles in the correct quadrant.

(2) Again because of program space, we neglect terms involving k^3 and except for one case those involving k^2 .

(3) On the first R/S if the number appearing (the difference in radians of the longitudes of the second and first stations) is greater than π , then key CHS, $h\pi$, 2, x, t, R/S. Otherwise we get the greater of the two geodesic distances between the stations. Of course, this is readily programmed but we do not have remaining available space.

We now repeat the above examples using the inverse solution.

| Place | Los Angeles | Jakarta | Tel Aviv |
|-------------------|-------------------------|-------------------------|-------------------------|
| Latitude | $34^\circ 03'$ | $-6^\circ 10'$ | $32^\circ 05'$ |
| Longitude | $-118^\circ 14'$ | $106^\circ 50'$ | $34^\circ 46'$ |
| Kilometers | 3961.6406 | 11344.3418 | 9259.2221 |
| Δ (meters) | 3.8 | 6.2 | 6.6 |
| Azimuth | $135^\circ 12' 18.62''$ | $78^\circ 34' 03.00''$ | $02^\circ 14' 33.65''$ |
| Δ AZ | 0.20" | 0.06" | 0.03" |
| Back AZ | $158^\circ 45' 02.66''$ | $155^\circ 07' 39.00''$ | $178^\circ 52' 19.11''$ |
| Δ B/AZ | 0.08" | 0.01" | 0.01" |

In this program, azimuths are less than 180° and give the angle from N to the eastbound portion of the geodesic.

The accuracy should be acceptable to all but the most demanding user. We pay for this accuracy in the usual coin of increased computing time. The reader may wish to program using a mean earth radius and the formulas of spherical trigonometry, as mentioned in Sec. 3.2, to persuade himself.

Because of lack of program space, the user must take account of three procedures:

- If both given latitudes are negative (Southern Hemisphere), change signs of *both* latitudes and *both* longitudes.
- If both stations have the same longitude (meridional arc), the program will show an error at step 044 ($1/\tan 0$). In this case add $0.01'$ to one longitude (0.01) and run from the beginning, although the solution is unstable for such small differences in longitude.
- Registers A, B, C, D are used both for initial and intermediate storage. If a new problem is to be run with the same first station, its coordinates must be restored. You can, however, store the coordinates also in S6 and S7, being careful to precede and follow by $f P \leftrightarrow S$.

4. REENTRY TRAJECTORIES

4.1. REFERENCES

- a. M. M. Moe, "An Approximation to the Re-Entry Trajectory," *ARS Journal*, January 1960, pp. 50-53.
- b. R. Blum, "Re-Entry Trajectories: Flat Earth Approximation," *ARS Journal*, April 1962, pp. 616-620.

4.2. DISCUSSION

For a body with zero lift and given weight-to-drag ratio (β), entering the upper atmosphere at time 0 with assigned altitude, velocity, and path angle, find at desired time intervals the subsequent range, altitude, velocity, and path angle to impact.

An "exact" solution (an analytic solution is not possible) requires the numerical integration of two second-order differential equations, both highly nonlinear. The technique is to merge a program for the functions of the differential equations with a slightly re-tailored version of Program 20, which solves fourth-order differential equations, also providing on a separate card an initialization program to determine values for the variables at the first time interval, $t = h$. This merging, retailoring, and initialization is a useful model for similar applications in other work, when a particular set of equations is to be solved frequently.

The equations adopted are those for a nonrotating round earth. There are three assumptions:

1. In the weight-to-drag ratio $\beta = mg/C_D A$, the drag coefficient is held constant, although it actually varies with Mach number;
2. Surface gravity g is used uncorrected for altitude by $(r_e/r)^2$, where r_e is the radius of the earth and r is the distance to the body from the earth's center;
3. The density of the atmosphere is approximated by $\rho(y) = 0.00237 \exp \{-y/24,000\}$ slug/ft³, where $y = r - r_e$ is the altitude in feet (Ref. a).

We have at Rand an on-line, time-sharing program in JOSS, written by D. C. Kephart, which performs the numerical integration using the fourth-order Runge-Kutta formulas and a time interval of 1 sec. Hence a convenient base of comparison with the simpler and coarser predictor-corrector approach of Program 20 is available.

4.3. EQUATIONS

The basic variables are:

- r = distance from earth's center (ft)
- ϕ = polar angle from initial vector to current vector
- V = speed of the body (ft/sec)
- θ = angle measured positively downward from the local horizontal to the velocity vector.

In these variables, the equations of motion are

$$\frac{1}{r} \frac{d}{dt} \left(r^2 \frac{d\phi}{dt} \right) = - \frac{F_D}{m} \cos \theta \quad (1)$$

$$\frac{d^2 r}{dt^2} = r \left(\frac{d\phi}{dt} \right)^2 - g + \frac{F_D}{m} \sin \theta, \quad (2)$$

where the drag force due to air is $F_D = \rho(y) V^2 C_D A / 2$. We also have

$$\begin{aligned} r(d\phi/dt) &= V \cos \theta, & dr/dt &= -V \sin \theta \\ V^2 &= (dr/dt)^2 + (r d\phi/dt)^2. \end{aligned} \quad (3)$$

Using the variables

$$\begin{aligned} x &= r_e \phi \text{ (range)} & y &= r - r_e \text{ (altitude)} \\ u &= x' & v &= y', \end{aligned}$$

the system of four first-order differential equations is

$$\begin{aligned} x' &= u & y' &= v \\ u' &= - \left[\frac{2v}{y + r_e} + \frac{g\rho(y)V}{2\beta} \right] u \end{aligned} \quad (4)$$

$$v' = \frac{y + r_e}{r_e^2} u^2 - g - \frac{g\rho(y)V}{2\beta} v ,$$

where

$$V^2 = (1 + y/r_e)^2 u^2 + v^2 .$$

As a matter of interest, it will be found by computing dV_0/dt and $d\theta_0/dt$ that for some reentry altitudes V can *increase* initially and θ can *decrease* (pitch-up). An example will illustrate these phenomena.

Turn now to the determination of x_1, y_1, u_1, v_1 at $t = h$, the first time increment, which are values needed for the method of Program 20. This will be programmed to initialize the numerical integration. We have

$$\begin{aligned} x_1 &= x_0 + u_0 h + \frac{u_0'}{2} h^2 & y_1 &= y_0 + v_0 h + \frac{v_0'}{2} h^2 \\ u_1 &= u_0 + u_0' h & v_1 &= v_0 + v_0' h , \end{aligned} \quad (5)$$

where h is the interval of integration (10 sec seems suitable).

The equations for the flat-earth approximation are found from (4) by putting $r_e = \infty$. The interested reader may wish to try programming this case along the lines of this section to compare the answers with those for a round earth.

4.4. PROGRAM NOTES

Program 20 is modified as follows:

1. At the beginning of LBL A, 4 is stored in registers D and E, replacing V_0 and θ_0 used during the initialization.
2. Most of LBL 4 is deleted, since we are working with 4 equations and we want to compute velocity and path angle for display.
3. The subroutine programming of u' and v' is straightforward, but we have had to use program steps for $g/2$ and g because storage registers are not available.

Example. Reentry conditions at $t = 0$ are

$$y_0 = 250,000 \text{ ft} \quad V_0 = 30,000 \text{ ft/sec} \quad \beta = 1000 \quad \theta_0 = 5^\circ .$$

The tabulation below shows values at intervals of 30 sec, although the step size used was 10. The numbers in parentheses are the outputs of Kephart's more refined integration procedure. His density function was used,

$$0.0027 \exp \{-y/23,500\} ,$$

instead of

$$0.00237 \exp \{-y/24,000\} ,$$

whose constants are stored on our data card (in S8 and S9).

After the "knee" of the trajectory the altitudes are in error by about 1000 ft low. The reason is that 10 sec is too great an interval in this region. If $h = 2$ sec is used, the maximum error in altitude reduces to about 80 ft and the other values are sensibly exact. And if $h = 1$ sec, the value used in Kephart's calculation, the maximum difference in altitude is 3.5 ft.

This is entirely of theoretical interest as a comparison of two methods of numerical integration: the fourth-order Runge-Kutta and the extended Hamming predictor-corrector method employed here. In the practical sense, the variation of the drag coefficient with Mach

| TIME (sec) | x RANGE (n mi) | y ALTITUDE (ft) | v VELOCITY (ft/sec) | θ ANGLE (deg) |

number, the departure of the atmosphere from the ideal one used in the calculation and, above all, the probably asymmetric ablation of the nose cone can vitiate such accuracy. Taking $h = 10$ sec is a reasonable choice that minimizes computing time while yielding acceptable accuracy for the purposes to which this program should be put.

5. SATELLITE ORBITAL ELEMENTS

5.1. REFERENCES

- a. R. H. Frick, W. I. Rumer, and E. H. Sharkey, *Trajectory and Orbit Plotter Instruction Manual*, The Rand Corporation, R-418-PR, October 1963.
- b. *Space Planners Guide*, USAF Air Force Systems Command, 1 July 1965 (For Official Use Only).

5.2. DISCUSSION

The orbital elements are

| | | |
|---|-----------------|------------|
| 1. Injection altitude | (n mi) | H_I |
| 2. Injection velocity | (ft/sec) | V_I |
| 3. Injection flight path angle | (deg) | γ_I |
| 4. Period | (min) | T |
| 5. Eccentricity | (dimensionless) | ϵ |
| 6. Semi-major axis | (n mi) | A |
| 7. Perigee altitude | (n mi) | H_p |
| 8. Apogee altitude | (n mi) | H_a |
| 9. True anomaly (at injection measured from apogee) | (deg) | ν_I |

The program below solves two of many possible problems:

- A. Given 1, 2, 3 find the remaining elements.
- B. Given 1, 7, 8 find the remaining elements.

Reference b uses a sequence of nomograms to solve these problems. Some of these nomograms are difficult to read with any precision because of close interval spacing for relatively large increments.

5.3. EQUATIONS

In Fig. 5.1 distances are measured in units of earth's radius (3437.9 n mi) and velocity in units of $\sqrt{R_E g_0}$ (25,943 ft/sec), the

Fig. 5.1—In-plane orbital elements

surface orbital velocity, and g_0 , the surface gravitational acceleration (32.174 ft/sec^2).

$$r = R/R_E, \quad v = V/\sqrt{R_E g_0} \quad (1)$$

$$C = R_I V_I \cos \gamma_I = RV \cos \gamma, \quad c = C/\sqrt{R_E^3 g_0} \quad (2)$$

$$E_0 = \frac{v^2}{2} - \frac{g_0 R_E^2}{R}, \quad E = E_0/R_E g_0 \quad (3)$$

$$\rho^2 = \left(\frac{1}{r_I} - \frac{1}{c^2} \right)^2 + \frac{\tan^2 \gamma_I}{r_I^2} \quad (4)$$

The orbital period is

$$T_0 = 2\pi \sqrt{\frac{R_E}{g_0}} |-2E|^{-3/2} \quad (5)$$

Other pertinent relations are

$$\frac{1}{r} = \frac{1}{c^2} - \rho \cos(\theta - \gamma_I) \quad (6)$$

$$\tan \gamma = -r \rho \sin(\theta - \gamma_I) \quad (7)$$

$$\frac{1}{r_a} = \frac{1}{c^2} - \rho, \quad \frac{1}{r_p} = \frac{1}{c^2} + \rho \quad (8a, 8b)$$

where r_a , r_p are the apogee and perigee distances,

$$\epsilon = \frac{r_a - r_p}{r_a + r_p} \text{ (eccentricity)} \quad (9)$$

$$a = \frac{r_a + r_p}{2} \text{ (semi-major axis)} \quad (10)$$

5.4. PROGRAM NOTES

Flag F3 (set by digit entry, cleared by test) is used to direct the program to Problems A or B. The program flow for Problem A (equation numbers in parentheses) is:

1. H_I , LBL A, GTO LBL 0 (1), r_I
2. V_I , LBL B, GTO LBL 1 (1), v_I
3. γ_I , LBL C, GTO LBL 2, γ_I
4. LBL e (2), $1/c^2$, (3), $|E|$ (total energy/non-dim.)
5. LBL D (8b), H_p
6. LBL E (8a), H_a
7. LBL a (5) T_0
8. LBL b (9), ϵ
9. LBL c (10), A
10. LBL d (7), v_I

This program can be appreciably shortened by a judicious use of subroutines. A suggested exercise is to rewrite it to see how many problems other than A and B can be packed on one card.

6. SATELLITE TRACKING

6.1. REFERENCE

- a. R. Henson, "Computerized Satellite Tracking," *73 Magazine*, February 1977.

6.2. DISCUSSION

Amateur radio operators make extensive use of OSCARS* (Orbiting Satellites Carrying Amateur Radio) for long-range communications. The OSCARS are in near-circular, sun-synchronous polar orbits at an altitude of about 1500 km. OSCAR comes within range of any given spot on earth twice each day, local morning heading south and local evening heading north, and may be within range for as much as 25 min.

An ephemeris provides time and longitude of orbital equatorial crossings (EQX). The problem is: Given the latitude and longitude of a ground station, determine whether or not a given orbit can be viewed and, if so, find the time the bird rises over the horizon and from then on determine its range, bearing, and elevation at desired times until it disappears below the horizon. Figures 6.1 and 6.2, prepared by W. B. Graham (K6QB) of The Rand Corporation, show an elegant solution for his station in Pacific Palisades, California. (See examples below.)

The problem is clearly of military as well as amateur interest.

6.3. EQUATIONS

Notation:

A = station latitude (north only)

B = station longitude (- if west)

β = orbital inclination measured counterclockwise from the equator (<90° prograde, >90° retrograde)

*For details on present and future OSCARS, see a series of articles in *QST* magazine (ARRL) starting with the January 1977 issue (Vol. 61, No. 1).

Fig. 6.1 — OSCAR 7 ascending

Azimuth and elevation of OSCAR 7 from Pacific Palisades, Ca.
as a function of time (t , minutes) after
Northbound Equatorial Crossing (EQX, E°)
For: $12^\circ \text{E} < \text{EQX} < 110^\circ \text{E}$

Fig. 6.2— OSCAR 7 descending

H = orbital altitude (n mi)

T = orbital period (min)

α = latitude of subsatellite point (SSP) at time t

γ = longitude of SSP at t

t = time from EQX (min)

γ_0 = longitude of EQX northbound (- if west, t = 0 at this node)

R_E = earth's radius (3437.9 n mi)

D_0 = arc from station to ascending node (EQX)

D_1 = arc to point of tangency of suborbit with latitude β

D_* = arc to SSP of closest approach

D = arc to SSP

t_* = time of closest approach

$t_* + \Delta t_*$ = time to rise above (go below) the horizon

θ = bearing from station north

ϕ = elevation above horizon

R = range from station to satellite (n mi).

By the law of sines,

$$\alpha(t) = \sin^{-1} \left[\sin \beta \cdot \sin (360 t/T) \right]. \quad (1)$$

By the law of cosines,

$$\gamma(t) = \cos^{-1} \left[\cos (360 t/T) / \cos \alpha(t) \right] - \frac{t}{4} + \gamma_0, \quad (2)$$

where $t/4$ is the correction for the earth's rotation. Also by the law of cosines,

$$D(t) = \cos^{-1} \left[\sin A \cdot \sin \alpha + \cos A \cdot \cos \alpha \cdot \cos (B - \gamma) \right]. \quad (3)$$

The equations for θ , ϕ , and R are:

$$\theta(t) = \cos^{-1} \left[\frac{\sin \alpha - \sin A \cdot \cos D}{\cos A \cdot \sin D} \right]. \quad (4)$$

$$\phi(t) = \tan^{-1} \left[\frac{\cos D - 1/(1 + H/R_E)}{\sin D} \right]. \quad (5)$$

$$R(t) = (H + R_E) \sin D / \cos \phi. \quad (6)$$

The above equations are essentially those of Ref. a, except for (6).

Critical times are dealt with by the following equations (which are somewhat in error because their derivation assumes the suborbital trace of the satellite is a great circle, which is not true on a rotating earth). For the time t_* of closest approach,

$$t_* = \frac{T}{360} \tan^{-1} (\cos D_1 / \cos D_0), \quad (7)$$

and the incremental times to zero elevation are

$$\Delta t_* = \pm \frac{T}{360} \cos \bar{D} / \cos D_*, \quad (8)$$

where \bar{D} is the arc length to the SSP at zero elevation and

$$\cos \bar{D} = 1/(1 + H/R_E). \quad (9)$$

Finally, the period in minutes is

$$T = \frac{2\pi}{60} \sqrt{\frac{R_E}{g}} \left(1 + \frac{H}{R_E} \right)^{3/2}. \quad (10)$$

6.4. PROGRAM NOTES

1. 045, 046: Change β to first quadrant to get latitude of orbit tangency.

2. 115, 116: For retrograde orbit, subtract in (2).
3. 117, 118, 119: These steps produce the sgn of t (± 1), since the HP-67 does not have this signum function.
4. 120, 121: For $t < 0$, south of the equator, move time backward so that posigrade and retrograde orbits reverse in getting SSP longitude by (2).
5. LBL ϕ corrects longitude if outside $(-180, +180)$, $\gamma > 180$ becomes $-360 + \gamma$, and $\gamma < -180$ becomes $360 + \gamma$.
6. LBL 1 gets bearing clockwise from station north.

Example 1. In Fig. 6.1, the ground station is at $34^\circ 03'N$ and $118^\circ 33'W$. The satellite is retrograde at an altitude of 790 n mi and has an inclination of 102° . Track the satellite when in view if the EQX is $110^\circ W$ at time 0.

Solution.

34.03 f H (34.05) STO A; 118.33 f H (118.55) CHS
STO B; 790 STO C; 102 STO D; 100 CHS STO E;
-1 h STI.

A: $T = 115.11$, $t_* = 11.68$, -29.74 (will come in view).
R/S: RCL 5, $\gamma = -100.39$; RCL 4, $\alpha = 1.31$ (SSP)
R/S: RCL 3, $t = 0.043$; RCL 7, $\theta = 148.72$, RCL 8, $\phi = -1.27$

Time t for first appearance is slightly small. Try $t = 1$
STO 3, PRESS B, RCL 8 and get $\phi = 0.51$. Try $t = 0.8$ and get
 -0.12 , which is good enough. The following table is prepared
by successively storing t in 3 and recalling 7, 8, 9:

| <u>t(3)</u> | <u>$\theta(7)$</u> | <u>$\phi(8)$</u> | <u>R(9)</u> (n mi = 1.1515 stat mi) |
|-------------|-------------------------------|-----------------------------|-------------------------------------|
| 0.8 | 148.40 | -0.12 | 2842 |
| 4 | 144.56 | 11.47 | 2154 |
| 8 | 132.20 | 34.11 | 1380 |
| 12 | 62.63 | 60.68 | 1014 |
| 16 | 1.62 | 31.70 | 1435 |
| 22 | 348.65 | 2.69 | 2654. |

These values are plotted as solid bullets in Fig. 6.1.

Example 2. All values are those of Example 1, except the EQX is 70°E . Hence the satellite will approach Pacific Palisades from the north.

Solution. Proceed as before. Note $T/2 \doteq 57.5$ min and STO 3, Press B, RCL 7, $\theta = -124.39$ is the descending node (EQX, moving south). Time will now be measured positive to the south of the equator. STO -124.39 in register E. Change the sign of the inclination β to minus and STO D. Now go back to square one and redo the problem from LBL A on. The results are tabulated below and again plotted as solid bullets in Fig. 6.2 for comparison.

| <u>t</u> | <u>t(corr.)</u> | <u>θ</u> | <u>ϕ</u> | <u>R</u> (stat mi) |
|----------|-----------------|----------------------------|--------------------------|--------------------|
| -22 | 35.5 | 19.14 | -.19 | 2847 |
| -18 | 39.5 | 23.88 | 14.95 | 1991 |
| -14 | 43.5 | 36.65 | 41.33 | 1241 |
| -12 | 45.5 | 61.85 | 61.46 | 1008 |
| -10 | 47.5 | 136.24 | 65.43 | 981 |
| -6 | 51.5 | 181.04 | 28.90 | 1506 |
| -2 | 55.5 | 188.51 | 8.23 | 2323 |
| +5 | 58.0 | 190.72 | -.47 | 2866 |

Ephemeris EQXs are given in ZULU time (GMT or UTC - Universal Coordinated Time for the radio amateur). Correct for local station time.

7.2. DISCUSSION

Reference a deduces an integral and constructs tables to assess the *expected* outcome of a one-sided, time-limited battle in which a set of armament-limited interceptors engages a set of defenseless penetrating bombers. The formulation also applies to a set of vessels transiting a minefield where each mine has a fixed number of warheads of some description. There are undoubtedly other military applications.

Builder's original paradigm is preferred. At the beginning of a hunt, there are A deer and B hunters, each of the hunters armed with m rounds of ammunition. Encounters are at random with parameter λ . A hunter can expend only one round on each engagement, with kill probability p. The hunt lasts T units of time.

In Ref. a, the parameters adopted are

$$j = \lambda p B T \quad k = p m B / A , \quad (1)$$

which provide a bridge to this discussion. The parameter j is the potential number of lethal encounters per deer during the hunt, based upon the expected encounter rate, while k is the potential number of lethal encounters per deer based upon the total hunter armament. The parameters λ and p are perhaps the more natural ones to employ.

A much simpler approach to finding the expected values than that of Ref. a is adopted here. This approach is adequately illustrated by the cases $m = 1$, $m = 2$.

For $m = 1$,

$$\frac{da}{dt} = -\lambda p a b \quad \frac{db}{dt} = -\lambda a b, \quad (2)$$

where a and b are, respectively, the number of deer and the number of armed hunters remaining at time t . Division gives a first integral $a = pb + \alpha$, where $\alpha = A - pB$. Whence

$$a(t) = \frac{A(A - pB)}{A - pB \exp \{-(A - pB) \lambda t\}}, \quad (3)$$

and $a(t)/A$ is precisely the P_s of Ref. a if (1) is used.

The a and b found by (2) were called the *expected* values. Actually they are the *deterministic* values. Using the methods of Ref. b (p. 118), which set up a partial differential equation for the moment-generating function,

$$\frac{d\mu_{10}}{dt} = -\lambda p \mu_{11} \quad \frac{d\mu_{01}}{dt} = -\lambda \mu_{11}, \quad (4)$$

where μ_{10} , μ_{01} are, respectively, the means or expected values of a and b , and μ_{11} is the correlation between a and b . Hence for (4) to agree with (2) we must have

$$\mu_{11} = \mu_{10} \cdot \mu_{01}$$

or $\text{Exp}(ab) = \text{Exp}(a) \cdot \text{Exp}(b)$. This is not true because the population sizes are mutually dependent. (See Ref. c, p. 184.) Consequently, we proceed with the understanding that we are dealing with deterministic values rather than expected values.

Turn to the case $m = 2$. At time t the values are a , b_1 , b_2 , where b_1 hunters have one round left and b_2 still have one round pouched. The deterministic equations are:

$$\frac{da}{dt} = -\lambda p a (b_1 + b_2), \quad \frac{db_1}{dt} = -\lambda a b_1 + \lambda a b_2, \quad \frac{db_2}{dt} = -\lambda a b_2. \quad (5)$$

Two integrals are found immediately:

$$a - pb_1 - 2pb_2 = A - 2pb \quad (6)$$

$$b_1 = -b_2 \ln b_2/B .$$

Whence,

$$\frac{db_2}{dt} = -\lambda pb_2^2 [2 - \ln b_2/B] - \lambda b_2 (A - 2pb) . \quad (7)$$

For particular values of the parameters, (7) is readily integrated by Program 11 of the HP-67 Math Pac 1. The results agree exactly with those of the table for $m = 2$ in Ref. a.

In principle, for $m > 2$ numerical integration is possible. In practice this would be very time-consuming, if not infeasible, for the HP-67.* The next section provides a completely different, although *heuristic*, approach.

7.3. EQUATIONS

Again take $m = 2$. (The symmetric equations to be derived are readily extended to a general m .) On each encounter, A decreases on the average by p . Hence $a(n) = A - np$ is the expected number of deer just after the n th encounter. The average time to the next encounter is $\Delta t = 1/(\lambda a(n) \cdot b(n))$, where $b(n) = b_1(n) + b_2(n)$ is the remaining number of armed hunters after the n th encounter. Then

$$b_1(n+1) = b_1(n) - 1 , \quad b_2(n+1) = b_n$$

with probability $b_1(n)/b(n)$, and

$$b_1(n+1) = b_1(n) + 1 , \quad b_2(n) = b_2(n) - 1$$

with probability $b_2(n)/b(n)$.

* But see Sec. 20 for $m = 3, 4$ application.

$m = 4$
 $A = 10$
 $B = 20$
 $\lambda = 1/5$
 $P = 1/4$
 $k = 2$
 $J = T$

Fig. 2.1—Program vs Ref. (a)

and

$$b_1 + 2b_2 + 3b_3 + 4b_4 = 40.00 ,$$

which is the expected number of remaining rounds.

7.4. PROGRAM NOTES

1. The program is designed to show the running history of the hunt by successive engagements. A PAUSE of 1 sec displays the engagement time and the remaining expected number of targets. If more time is needed to record, key h SF 1, which will give a 5-sec f -x- flashing followed by a 1-sec PAUSE. At any time, stopping the program by R/S permits an examination of the current status of the hunt by

t(RCL 9) , a(RCL A) , b(RCL B) , b₄(RCL 8) ,

b₃(RCL 6) , b₂(RCL 4) , b₁(RCL 2) .

2. If LBL A directs action to the correct label for n by dissecting the input R,n and using CTO (1).

3. Extensive use of subroutines leads to program economy.

4. It will also be remarked that a systematic use of label and register addresses eases the programming.

8. A BOMBER PENETRATION MODEL (DEFENDED BOMBERS)

8.1. REFERENCES

None.

8.2. DISCUSSION

This penetration model is offered solely as an example of how the HP-67 can assist the analyst in his preliminary study of the factors bearing on a problem and how these factors interact. Model-making is, or rather should be, an art form drawing the essential elements from reality and illuminating their articulation. The author holds to the view that an initial model should be economical and transparent. The ornaments come later.

A group of bombers with integrated fire control for mutually supporting self-defense against interceptors makes a corridor penetration to a set of targets. The payload of a bomber can be divided at pleasure between defense missiles (AAM) and ground attack munitions (ASM). This loading is decided prior to the mission by choosing the number of AAM to be fired against each interceptor based on the expected number to be encountered. At equal intervals of time during the penetration, a clump of interceptors comes within range of the bombers' AAMs. *The bombers fire first.* Each of the surviving interceptors of the clump makes a single pass, allocating fire uniformly over the bombers, and then withdraws from the battle. As the battle progresses, more and more AAMs are fired per surviving bomber at the new interceptor clumps.

What bomber loading maximizes ASMs delivered on target?

8.3. EQUATIONS

B_0 = initial bomber force

B_1 = bombers after first intercept encounter

I = total interceptors

I_1 = interceptors after first encounter

$K = A + r \cdot S$, the payload constant

r = ratio of ASM to AAM weights

k = AAMs expended per interceptor encountered

Q = probability an AAM will miss an interceptor

I = interceptors per clump

q = probability an interceptor will miss its target

N = duration of the penetration with unit of time
the interval between interceptor mass attacks

T = ASMs on target

$$y^{**x} = y^x.$$

Then

$$B_{n+1} = B_n \cdot q^{**}(I \cdot Q^{**}k/B_n) \quad (1)$$

because $I \cdot Q^{**}k$ interceptors survive and this divided by B_n is the expected number of passes per bomber.

The number of missiles fired per bomber on the n th engagement equals kI/B_n . Hence the number of AAMs per surviving bomber to target is

$$A = kI(1/B_1 + 1/B_2 + \dots + 1/B_N), \quad (2)$$

If the planning assumptions were realized in combat. The number of bombers surviving to target equals B_{N+1} , since after the last engagement by B_N they in turn receive return fire. Finally,

$$T = B_{N+1}(K - A)/r. \quad (3)$$

As k increases, B_{N+1} decreases but $K - A$ increases. This tradeoff implies the existence of a k to maximize T .

For the purpose of attempts to make an approximate analytical solution to (3) for each k , the effect of k on the return fire is neglected.

quickly, and (2) this exploration is informative since it shows the sensitivity of the outcomes to k (as well as to the other parameters).

Example.

$B = 10$, $K = 30$, $r = 3$, $Q = 1/2$, $I = 10$, $q = 1/2$, $N = 3$

| <u>k</u> | <u>A</u> | <u>B₄</u> | <u>T</u> |
|----------|----------|----------------------|----------|
| 2 | 7.30 | 5.31 | 40.19 |
| 1 | 4.72 | 1.95 | 16.40 |
| 3 | 9.87 | 7.52 | 50.47 |
| 4 | 12.55 | 8.73 | 50.78 |
| 3.5 | 11.19 | 8.22 | 51.54 |

Note how flat the bombs-on-target curve is for $k = 3$ to 4. Going from $k = 3.5$ to 4 decreases bombs on target by 1.5 percent, but *increases* bombers saved by 5 percent of the original force. This saving is not trivial if bombers are to be recycled for follow-on attacks. It illustrates the insight that quickly prepared "toy" models can provide.

9. DAMAGE PROBABILITIES, PVN AND QVN TARGETS

9.1. REFERENCES

- a. D. C. Kephart, *Some Aids for Estimating Damage Probabilities in Attacks Against Targets with P and Q Vulnerability Numbers*, The Rand Corporation, R-1168-PR, March 1973 (For Official Use Only).
- b. *Physical Vulnerability Handbook--Nuclear Weapons*, Defense Intelligence Agency, 1975 update.

9.2. DISCUSSION

The program in this section was prepared by D. C. Kephart of The Rand Corporation. He has also written the program for Texas Instruments' SR-52 hand calculator.

The program gives damage probabilities for nuclear weapons applied against PVN and QVN point targets at the optimal airburst height. For these two classes of targets 'psi' is given by:

$$\text{Overpressure, psi} = 1.1216 \times 1.2^v \quad (v = \text{adjusted PVN})$$

$$\text{Dynamic pressure, psi} = 0.02893 \times 1.44^v \quad (v = \text{adjusted QVN})$$

9.3. EQUATIONS

Notation

VN.K = Vulnerability number

V = Integer part of VN.K

K = Fractional part of VN.K = [K-factor]/10

w = Warhead yield in kilotons

C = Weapon CEP in feet

A = VN adjustment

v = V + A adjusted vulnerability number

R = Weapon radius in feet

P = Single-shot probability of damage (SSPD)

Formulas for PVN

$$S = \frac{K}{2} \left(\frac{20}{w}\right)^{1/3} + \left\{ \left[\frac{K}{2} \left(\frac{20}{w}\right)^{1/3} \right]^2 + 1 - K \right\}^{1/2}$$

$$A = \ln(S^2)/\ln(1.2)$$

$$v = V + A$$

$$R = w^{1/3} [6383.35 \times 0.8836^v] \quad \text{if } v \leq 20.5$$

$$R = w^{1/3} [1900.05 \times 0.9368^v] \quad \text{if } v > 20.5$$

$$P = 1 - \exp \left\{ -R^2/2/[C^2/\ln(4) + 0.04R^2] \right\}$$

Formulas for QVN

S satisfies the cubic equation

$$S = [SK \left(\frac{20}{w}\right)^{1/3} + 1 - K]^{1/3}$$

$$A = \ln(S^3)\ln(1.2^2)$$

$$v = V + A$$

$$R = w^{1/3} [6561 \times 0.87918^v] \quad \text{if } v \leq 15.4$$

$$R = w^{1/3} [23.42 + 2736.9 \times 0.92883^v] \quad \text{if } v > 15.4$$

$$t = 1 - \exp \left\{ -R^2/2/[C^2/\ln(4) + 0.09R^2] \right\}$$

$$P = t \quad \text{if } t \leq 0.82$$

$$Q = 2.826t - 0.94t^2 - 0.866 \quad \text{if } t > 0.82$$

$$P = Q \quad \text{if } Q \leq 1$$

$$P = 1.0 \quad \text{if } Q > 1$$

9.4. PROGRAM NOTES

10. FOUR DEUCES (PRECISION 4.2-INCH MORTAR FIRE)

10.1. REFERENCES

- a. FT 4.2-F-1, *Firing Tables, Mortar, 4.2-Inch, M30*, Department of the Army, December 1954.
- b. FM 23-92, *4.2-Inch Mortar, M30*, Department of the Army, February 1961.

10.2. DISCUSSION

The 4.2-inch mortar, M30, is a rifled, muzzle-loaded weapon, known affectionately to the Army as the "four deuce." The tube, elevated at angles of 45° to 60° (800 mils to 1065 mils) delivers indirect fire to almost 5.5 kilometers, depending on the propellant charge, elevation, and round selected.

Indirect fire units use a meteorological message (a coded weather report) from division artillery in conjunction with unabridged firing tables to prepare firing data. As of 1961 (Ref. b) a rather time-consuming and largely manual procedure was used, which even sacrificed almost all tabular interpolation to save time and avoid errors. This section shows how the procedure of that era would have been simplified had a programmable hand-calculator been available then.

The primary task is to reduce the tables, which were based on range firings conducted at the Aberdeen Proving Grounds, to a set of formulas. This is accomplished by data fitting, a task for which the HP-67 is admirably suited if one has at hand Program 3 of the Standard Pac and Program 14 (Polynomial Approximation) of Stat Pac 1. Mark that this data fitting is purely empirical. It is based in no way on the physics and mathematics of exterior ballistics.

The only problem posed by the tailoring of formulas to number streams is the choice of the formula type to be used. Initial guidance is provided by plotting families of curves and staring at them. (See Sec. 21.)

The resulting formulas are simple and so is the required programming. You pay for this double simplicity but can exploit it. The large number of constants generated by fitting exceeds available

storage space. But because the program is short, there is space to put constants, sometimes rounded, in the program itself. This is program/storage tradeoff.

The next subsection gives formulas that correct the fire for nonstandard conditions, in the order in which they will be programmed. This is also the approximate order of the manual calculations in the examples of Ref. a. The program significantly modifies the methods of that reference in respect to automatic interpolations, allowance of difference in altitude of mortar and target, ballistic winds, and elevation corrections.

10.3. EQUATIONS

General

- (1) This program is restricted to the M30 firing the HE shell M329 with extension (long-range fire).
- (2) The range of charges is 25.5 to 41 and increments of 1/8 are permitted.
- (3) Elevations are restricted to 800 to 900 mils (μ), since the tables are so restricted for charges above 32.
- (4) Hence charge is selected so that 850 μ (47.81°) elevation gives the *approximate* desired range ($1 \mu = 360/6400^\circ = 0.05625 = 1/17.778$).
- (5) Meters rather than yards are used ($1 \text{ yd} = 0.9144 \text{ m}$).

Notation

- | | |
|----------|---|
| H_o | Altitude of mortar position in meters |
| R_o | Chart range in meters |
| R_1 | Range corrected for difference in altitude of mortar and target |
| R_2 | R_1 corrected for metro and ballistic factors |
| $R(800)$ | Range for $E = 800 \mu$, a function of charge m |
| A_o | Azimuth of fire (mortar to target) in mils, CW from N |

- E_0 850 μ , the initial elevation
- E_2 Corrected elevation (μ)
- C_0 The initial charge selected
- C_2 Corrected charge
- ω The angle of fall in mils (impact angle)
- T Powder temperature in F°
- VE Muzzle velocity error in ft/sec for lot used (0 if not known.
This can be obtained only from trial firings.)
- r Deviation in shell weight from $\begin{bmatrix} \square & \square \end{bmatrix}$ (-1, 0, +1).
(Weight is measured in squares and stamped on the shell.)
- H_T Altitude of target in meters
- H_M Altitude of meteorological data plane (MDP) in *feet*
- A_W Azimuth of ballistic wind in μ CW from N. (This is the
direction *from* which the wind blows. It is an average of
winds up to the maximum ordinate of the trajectory.)
- α Angle between A_0 and A_W - 3200 in degrees
- δ_0 Density of the air as percent of standard for the MDP altitude
- δ_1 Corrected density for mortar altitude relative to MDP
- W Ballistic wind in *miles per hour*
- d Drift deflection because of shell rotation (always to the
right)
- D Deflection correction, final (μ)
- ρ_1 Correction for range wind (tail or head), meters
- ρ_2 Correction for round weight, meters
- ρ_3 Correction for powder temperature, meters
- ρ_4 Correction for actual air density, meters
- ρ_5 Correction for VE , meters

$$\rho = -(\rho_1 + \rho_2 + \rho_3 + \rho_4 + \rho_5), \text{ meters}$$

P Change in muzzle velocity due to change in powder temperature (ft/sec)

Metro Msg

H_M , A_W , W , δ are known when the Metro Message is "solved." The message also gives air temperature, which is not relevant for mortar calculations. The message has 12 lines in addition to the heading. The initial digit is the standard altitude number. The correspondence is

| | | | | | | |
|-------------|------|-------|-------|-------|-------|-------|
| Alt. No. | 0 | 1 | 2 | 3 | 4 | 5 |
| Height (ft) | 0 | 600 | 1500 | 3000 | 4500 | 6000 |
| Alt. No. | 6 | 7 | 8 | 9 | 0 | 1 |
| Height (ft) | 9000 | 12000 | 15000 | 18000 | 24000 | 30000 |

The lines of the message give A_W , W , δ (and air temperature) appropriate for the maximum ordinate of the trajectory resulting from any particular combination of range, charge, and elevation.

For this program ($800 \text{ m} \leq E \leq 900 \text{ m}$, $R \geq 3250 \text{ m}$), always use line 4 except

| | |
|------------------------------|----------|
| $C = 25.5$ | Line 3 |
| $C = 41$ | Line 5 |
| $C \geq 36$ and $E \geq 850$ | Line 5 . |

Formulas

$$E_o = 850 \text{ m} \quad (1)$$

$$C_o = 11.932 \exp (0.000231 R_o) \quad (2)$$

$$\omega = (867 + 4C_o)(360/6400) \quad (3)$$

$$R_1 = R_o + (H_T - H_o)/\tan \omega \quad (4)$$

($R_1 > R_o$ if target is above mortar)

$$\delta_1 = \delta_0 - 0.003 (H_0/0.3048 - H_M) \quad (5)$$

(H_0 is changed from meters to feet)

$$\alpha = 0.05625 (A_W - 3200 - A_0) \quad (6)$$

$$d = 0.064 E_0 - (C_0 + 1)/2 \quad (7)$$

$$D = -[d + 0.8 W \sin \alpha] \quad (8)$$

(The tube is pointed for firing at $A_0 + D$)

$$\rho_1 = (0.325 C_0 - 4.682) W \cos \alpha \quad (9)$$

(The term in parentheses is the unit effect for a tail wind of 1 mph, Col. 15 of tables)

$$\rho_2 = (17.879 \ln C_0 - 72.914) r \quad (10)$$

(Unit effect in parentheses Col. 17)

$$\begin{aligned} P &= -23 + 0.68 T - 0.005 T^2, & T \leq 70^\circ \\ &= 15.29 - 0.48 T + 0.0038 T^2, & T > 70^\circ \end{aligned} \quad (11)$$

(Table of App. A of Ref. a, fitted)

$$\rho_3 = (16.3 - 2.5 \ln C_0) P \quad (12)$$

(Unit MV effect in parentheses Col. 18)

$$\rho_4 = (11.037 - 0.7293 C_0)(\delta_1 - 100) \quad (13)$$

(Unit 1 percent effect in parentheses Col. 16)

$$\rho_5 = (16.3 - 2.5 \ln C_0) \cdot VE \quad (14)$$

$$\rho = -(\rho_1 + \rho_2 + \rho_3 + \rho_4 + \rho_5) \quad (15)$$

(Note the - sign)

$$R_2 = R_1 + \rho \quad (16)$$

This is the corrected final range.

$$C_2 = 11.932 \exp (0.000231 R_2) \quad (17)$$

(This is the corrected charge for $E = 350$ ft.
It is to be rounded to the nearest 1/2
charge.)

$$R(800) = 52.51 + 81.73 C_2 + 2.96 C_2^2 - 0.043 C_2^3 \quad (18)$$

(Fitted from bottom line data of tables)

$$E_2 = 800 + [6.416 - 0.093 C_2][R(800) - R_2]^{0.712} \quad (19)$$

This is the final elevation at which to lay the tube. Note the correction of C_0 using $E = 850$ ft and the final R_2 . But then $E = 850$ ft is forgotten and the procedure is to go to new formulas to get E_2 with respect to the baseline elevation $E = 800$ ft. This procedure yields a small correction to the initial 850 ft.

Note: Because of lack of program/storage space, formula (11) is rewritten as

$$\begin{aligned} P &= -(0.02 \Delta T + 0.005 \overline{\Delta T}^2) & \Delta T \leq 0 \\ &= 0.05 \Delta T + 0.0038 \overline{\Delta T}^2 & T > 0, \end{aligned} \quad (20)$$

and the user enters $\Delta T = T - 70^\circ$, the deviation from the standard powder temperature with the proper sign.

Checks

To provide program verification, a step-by-step example is calculated manually. These results are then compared with the Army's

field procedure, which does not require interpolation and rounds off various values. Yards instead of meters are employed in these checks.

$R_o = 5320$ (nearest 10 yd) , $H_o = 1505$ ft , $H_T = 1210$ ft ,

$A_o = 4825$ ft , wgt = \square (r = -1) , $T = 55^\circ\text{F}$,

$VE = -12$ ft/sec.

Solving the Metro Message (heading and line 5),

| | |
|-----------|-------------|
| M 1 F 1 2 | 0 8 3 0 3 |
| 5 2 6 2 5 | 9 5 7 8 5 , |

we get: message from Station 1F, MDP = 1200 ft, as of 0830 hr; this is msg type 3 (for mortars); standard altitude for line 5 is 6000 ft; ballistic wind blows from 2600 ft, strength 25 mph; air density is 95.7 percent, and air temperature is 85°F.

The above conditions were taken from Ref. a. They could be realized, for example, at Hunter Liggett Military Reservation in California on a day in November with Santa Ana winds blowing. Use Map Series V895S, Sheet 1755 1 NW, 1:25000. Put the mortar position on Hill 1516 (66960 73900) and the target close to the junction of two dirt roads and almost in the bed of Fria Creek (62095 74000).

Note: Yards rather than meters are used below.

| <u>Quantity</u> | <u>Field Method</u> | <u>Formulas</u> |
|-----------------|---------------------|-----------------|
| R_o | 5300 | 5320 |
| H_o | 1500 | 1505 |
| E_o | 847 | 850 |
| C_o | 36.5 | 36.71 |
| ω | 1009 | 1014 |
| R_1 | 5255* | 5256 |
| δ_1 | 94.8 | 94.8 |
| d | 38 | 35.6 |
| D | -57 | -52 |
| ρ_1 | 113 | 114 |
| ρ_2 | 9 | 9 |
| ρ_3 | -15 | -11 |
| ρ_4 | 88 | 90 |
| ρ_5 | -91 | -96 |
| ρ | 104 | 106 |
| R_2 | 5151 | 5150 |

The field method now selects a new charge for which the adjusted range R_2 is bracketed by a 50-yd tabular interval in the tables. Interpolation is now used in general. Here we can read off

$$C_2 = 35.5 \quad E_2 = 854 \text{ ft.}$$

Formula (17) yields $C_2 = 35.41$. Round this to $C_2 = 35.5$ and obtain, via (18) and (19), $E_2 = 853 \text{ ft.}$

10.4. PROGRAM NOTES

*"When I know more of gunnery
Than a novice in a munnery,
I'll be the very model
Of a modern Major-General."*

- W. S. Gilbert, *The Pirates of Penzance*, 1879

*The field method corrects 5320 by $1/2$ the altitude difference in yards or by -50 yd. We have used the more accurate value -65 yd.

11. A LASER EQUATION

11.1. REFERENCE

- a. L. N. Peckham and R. W. Davis, *A Simplified Propagation Model for Laser System Studies*, Air Force Weapons Laboratory, Technical Report AFWL-TR-72-95, August 1972, ASTIA No. AD902736L.

11.2. DISCUSSION

The laser equation programmed in this section was brought to my attention by Lieutenant Colonel R. S. DeLaney, USAF. The equation applies to propagation in the atmosphere. A listing of the variables and parameters used in the equation shows the factors considered in it.

| <u>Symbol</u> | <u>Meaning</u> | <u>Units</u> |
|---------------|---|-----------------------|
| P | power | watts |
| R | range | km |
| I | average intensity | watts/cm ² |
| b | blockage factor | -- |
| K | thermal blooming factor | -- |
| α | atmospheric extinction | 1/km |
| k_1 | power reduction factor | -- |
| k_2 | beamspread factor | -- |
| λ | wavelength | microns |
| D | diameter of primary output mirror | meters |
| σ_{TR} | one sigma jitter/tracker | microradians |
| σ_{PL} | one sigma jitter/platform | microradians |
| σ_{BL} | one sigma jitter/boundary layer | microradians |
| σ_{AT} | one sigma jitter/atmosphere | microradians |
| θ | angle between beam and target normal | deg |

11.3. EQUATIONS

$$I = \frac{100 \cdot b \cdot K \cdot p \cdot \exp(-\alpha R) \cdot \cos \theta}{k_1 \cdot \pi R^2 [(0.9 k_2 \lambda/D)^2 + 4(\sigma_{TR}^2 + \sigma_{PL}^2 + \sigma_{BL}^2 + \sigma_{AT}^2)]} \quad (1)$$

The number 100 is needed to get the intensity at the target in watts/cm² when R is in kilometers.

We will program three problems:

- Given P and R, find I
- Given I and R, find P
- Given I and P, find R.

In effect, the program is a digitized nomogram.

We will use Newton's method to get R given I and P. We have

$$I = LPe^{-\alpha R/R^2}, \quad (2)$$

where

$$L = \frac{100 \cdot b \cdot K \cos \theta}{k_1 \cdot \pi [(0.9 k_2 \lambda/D)^2 + 4\sigma^2]}, \quad (3)$$

$$\sigma^2 = \sigma_{TR}^2 + \sigma_{PL}^2 + \sigma_{BL}^2 + \sigma_{AT}^2.$$

We want the root of

$$f(R) = LPe^{-\alpha R/R^2} - I = 0. \quad (4)$$

then

$$f'(R) = -(\alpha + 2/R) LPe^{-\alpha R/R^2}, \quad (5)$$

$$R_{i+1} = R_i + \frac{LPe^{-\alpha R_i/R_i^2} - IR_i^2}{LPe^{-\alpha R_i/R_i^2}(\alpha + 2/R_i)}. \quad (6)$$

The only point of interest is the determination of a good starting value R_0 . The function $e^{-\alpha R}/R^2$ is concave upward and extremely flat for even moderately large R . If an initial R_0 is picked that is greater than R , it may well happen that the flat tangent projected backward will generate negative values for the successive R_1 .

For the root of (4),

$$R^2 = Ae^{-\alpha R}, \quad A = LP/I.$$

A first approximation is \sqrt{A} , but this is clearly too large. But taking

$$R_0 = \sqrt{A} e^{-\frac{\alpha\sqrt{A}}{2}}, \quad (7)$$

a value smaller than the actual root is found.

The program also computes the illuminated area by

$$0.01 \pi R^2 [(0.9 K_2 \lambda/D)^2 + 4\sigma^2] \sec \theta. \quad (8)$$

11.4. PROGRAM NOTES

(1) The program is an example of the use of the flag F3 to find the solution of any one of three problems. The program structure is:

| <u>P</u> | <u>R</u> | <u>I</u> |
|-------------|-------------|-------------|
| *fLBLA | *fLBLB | *fLBLC |
| hF?3 | hF?3 | hF?3 |
| GT01 | GT02 | GT03 |
| Calculate P | Calculate R | Calculate I |
| *fLBL1 | *fLBL2 | *fLBL3 |
| STO A | STO B | STO C |
| hRTN | hRTN | hRTN |

Flag F3 is set by data entry, and cleared by test. If you key P and press A, F3 is set, P is stored in A, and F3 is cleared. If you then key I and press C, I is stored in C. Now press B. Since F3 is not set, the step "GTO 2" is skipped and R is calculated.

(2) For the preceding problem, an "h PAUSE" shows the successive steps in the convergence to two decimal places. When P is large and/or I is small, the convergence is slow because the value of R_0 from (7) is small. You can speed up convergence by choosing an R_0 that is large but still smaller than the expected final root. Then execute the sequence: Key R_0 , STO B, GTO 0, R/S.

Example. Let the parameters be:

$$b = 0.9, K = 1, \alpha = 0.1, k_1 = 1.5, k_2 = 20/9,$$

$$\lambda = 3.6, D = 1, \text{ each of the four sigmas} = 4 \text{ (so that}$$

$$\sigma^2 \text{ is } 64), \theta = 60^\circ. \text{ Then PRESS E to initialize.}$$

$$(1) P = 10^6 \text{ (EEX 6), PRESS A, } R = 4, \text{ PRESS B.}$$

$$\text{Now PRESS C to get } I = 1299.60 \text{ watts/cm}^2.$$

$$\text{PRESS D to get } 309.47 \text{ cm}^2 \text{ for the illuminated area at this range.}$$

$$(2) 4, \text{ PRESS B, } 1299.60, \text{ PRESS C. PRESS A to get}$$

$$P = 1\,000\,002.64 \text{ watts (because of roundoff in I).}$$

$$(3) 10^6, \text{ PRESS A, } 1299.60, \text{ PRESS C. PRESS B to get}$$

$$R = 4 \text{ after two iterations (3.99, 4.00).}$$

12. SHAKING THE DICE (A WAR GAMING EXAMPLE)

12.1. REFERENCE

- a. E. W. Paxson, *Partially Discriminatory Mortar Fire*, The Rand Corporation, P-5807, February 1977.

12.2. DISCUSSION

In manual war gaming, people instead of computers make the tactical decisions depending on the situation. Yet there are recurring events, such as firefights or air intercepts, whose outcomes must be assessed systematically on the basis of agreed-upon rules and planning factors. The assessment consists of taking a sample from a probability distribution function for outcomes, since the game cannot move on without a definite result. War gamers call this "shaking the dice." It will not do to say, "The probability is 0.4 that at least three tanks of a company of 10 will be destroyed." The game demands a statement such as, "In this firefight 3 tanks were immobilized and one was set afire."

In any game, there are usually large numbers of recurring events of the same type. One expects that the results for this set of events will average out--giving the mean behavior of the model underlying the event type. To clarify this statement, the simple fundamental principle of the Monte Carlo method (sampling from a probability distribution) is invoked. For example, suppose an event can have four outcomes $0_1, 0_2, 0_3, 0_4$ with respective probabilities p_1, p_2, p_3, p_4 , where $p_1 + p_2 + p_3 + p_4 = 1$. Put $P_1 = p_1, P_2 = p_1 + p_2, P_3 = p_1 + p_2 + p_3, P_4 = p_1 + p_2 + p_3 + p_4 = 1$. Take a large number M of random numbers uniformly distributed over the interval $(0, 1)$. By the Law of Large Numbers, one expects, then, that of the M random numbers,

$p_1 M$ will be in the interval 0 to P_1 ,

$p_2 M$ will be in the interval P_1 to P_2 ,

$p_3 M$ will be in the interval P_2 to P_3 ,

$p_4 M$ will be in the interval P_3 to 1.

This section shows by an example how hand calculator programs can provide assessments of this nature to speed up the play of manual war games.

A game (or series of games) is set up to test the behavior in a full tactical environment of an innovative weapon system, which is to destroy enemy armor as part of a combined arms force.

The proposed system envisages a new type of mortar round that has a heat-seeking sensor head controlling the maneuver of the round to a target during the steep terminal phase of the trajectory. These rounds are ripple-fired at a set of armored targets, picking targets at random. The sensor head will reject targets previously set afire or exploded (K-kills) to avoid the moth-and-flame effect. But previously immobilized vehicles (M-kills) may wastefully absorb rounds that home on the still-warm engines. Such overkill is a common battlefield event.

If at any time t during the engagement there are j vehicles still moving and k vehicles either still moving or immobilized by previous fire, then the probability $P(j, k, t)$ of the state (j, k) at time t can be determined analytically (see Ref. a). But the analysis is complex, as are the resulting formulas for $P(j, k, t)$. For use in war gaming, it would still be necessary to sample with respect to $P(j, k, t)$. It is much more economical to adopt the procedure of the following subsection.

12.3. EQUATIONS

Let r be the probability that a round gets an M-kill, immobilizing the target. Let s be the probability of a K-kill, with the target exploded or set afire. Initially, there are A moving targets, against which N rounds can be fired during the target exposure interval.

Then the state changes per round, with their associated probabilities, are shown in the following table, remembering that of k targets one is picked at random:

| State Change | Probability | Reason |
|-------------------------------------|----------------------|---|
| $(j, k) \rightarrow (j, k)$ | $p_1 = 1 - s - rj/k$ | No K-kill <i>and</i> no M-kill of a moving target |
| $(j, k) \rightarrow (j - 1, k)$ | $p_2 = rj/k$ | M-kill of a moving target, k does not change |
| $(j, k) \rightarrow (j - 1, k - 1)$ | $p_3 = sj/k$ | K-kill of a moving target, k reduces by 1 |
| $(j, k) \rightarrow (j, k - 1)$ | $p_4 = s(1 - j/k)$ | K-kill of an immobilized target |

The corresponding bounds in the interval (0, 1) are

$$P_1 = 1 - s - rj/k, P_2 = 1 - s, P_3 = 1 - s + sj/k, P_4 = 1.$$

Pseudorandom numbers over the interval (0, 1) will be generated by the multiplicative linear congruential method. Let R_0 be the initial "seed," a seven-digit decimal fraction. Let m be the multiplier, and let R_i be the i th pseudorandom number generated. Then

$$R_{i+1} = \text{fractional part of } (mR_i).$$

In the Hewlett-Packard Stat Pac 1 (section 04), the values $R_0 = 0.5284163$ and $m = 997$ are used. With these choices, the number of *different* random numbers before returning to R_0 (the period of the sequence) is 500,000. The sequence passes the standard tests for randomness.*

12.4. PROGRAM NOTES

Figure 12.1 provides the logical flow of the programming.

It is essential to save the last random number, to be used as the "seed" for the next evaluation.

* Other "good" pairs are: $R_0 = 0.1111111$, $m = 291$; $R_0 = 0.7742713$, $m = 997$.

13. OPTIMUM ALLOCATION OF RESOURCES

13.1. REFERENCES

- a. Hanan Luss and Shiv K. Gupta, "Allocation of Effort Resources Among Competing Activities," *Operations Research*, Vol. 23, No. 2, March-April 1975.
- b. A. Charnes and W. W. Cooper, "The Theory of Search: Optimum Distributions of Search Effort," *Management Science*, Vol. 5, 1958.

13.2. DISCUSSION

This is a topic in nonlinear (convex) programming. The bibliography of Ref. b indicates optimum search as one military motivation for the study of programming of this nature. Another military application asks for the optimum allocation of weapons to a target system organized into classes of targets of given number and value for which the weapons' kill probabilities differ. Civilian applications arise in allocating advertising budgets, portfolio selection, and budgeting (Ref. a).

The problem is formulated as follows. Let B be the available resources to be allocated to N activities in the amounts x_1, x_2, \dots, x_N , where

$$x_1 + x_2 + \dots + x_N = B, \quad x_i \geq a_i \geq 0. \quad * \quad (1)$$

If x_i is applied to activity i , the return on the investment is $Q_i(x_i)$, which is a differentiable and strictly concave increasing function. For example, in the weapon allocation application, if there are T_i targets in class i all of value V_i , and if the SSPK is P_i , then

$$Q_i(x_i) = T_i V_i \left[1 - (1 - P_i)^{x_i/T_i} \right], \quad (2)$$

* Higher authority or other considerations may dictate that some activities be assigned minimum (nonzero) resources.

since on the average x_i/T_i weapons are applied to each target and the square brackets contain the kill probability per target. Figure 13.1 shows $[1 - (1 - 0.5)^{x/20}]$. Note the rapid decrease in marginal returns for the larger values of x . One "standard" form for $Q_i(x_i)$ is

$$Q_i(x_i) = S_i [1 - \exp(-m_i x_i)] , \quad (3)$$

which yields (2) if $S_i = T_i V_i$ and $m_i = -(1/T_i) \ln(1 - P_i)$.

We now want to maximize

$$R = Q_1(x_1) + Q_2(x_2) + \dots + Q_N(x_N) \quad (4)$$

subject to (1).

13.3. EQUATIONS

From (3),

$$\partial Q_i(x_i) / \partial x_i = S_i m_i \exp(-m_i x_i) . \quad (5)$$

Reindex the activities so that $S_i m_i \geq S_{i+1} m_{i+1}$, which are the marginal returns at the origin. Introduce the Lagrangian multipliers M_ℓ and maximize

$$\sum_{i=1}^{\ell} \left\{ Q_i(x_i) - M_\ell \cdot \left(\sum_{i=1}^{\ell} x_i - B \right) \right\} .$$

To this end

$$\frac{\partial Q_i(x_i)}{\partial x_i} = M_\ell = \frac{\partial Q_j(x_j)}{\partial x_j} , \quad i, j = 1, \dots, \ell$$

express the marginal equilibrium. We find that the successive M_ℓ are connected by

$$M_{\ell+1}^{***} \sum_{i=1}^{\ell+1} 1/m_i = (S_{\ell+1} m_{\ell+1})^{***} (1/m_{\ell+1}) \cdot M_{\ell}^{***} \sum_{i=1}^{\ell} 1/m_i, \quad (6)$$

where "***" means "to the power" and $M_1 = S_1 m_1 \exp(-Bm_1)$.

The solution algorithm is to stop at that ℓ for which

$$S_{\ell+1} m_{\ell+1} \leq M_{\ell+1}. \quad (7)$$

Then

$$x_i^* = \frac{1}{m_i} \ln \frac{S_i m_i}{M_{\ell}}, \quad i = 1, \dots, \ell \quad (8)$$

and the maximum return is

$$R_{\ell}^* = \sum_{i=1}^{\ell} \frac{S_i m_i - M_{\ell}}{m_i}. \quad (9)$$

Figure 13.2 shows the physical realization of this algorithm. The Q that gives the maximum return is used first, then the Q that yields the next-highest return, and so on. Find the x_i^* where the slopes of the Q -curves are all equal, since taking a unit of resources from one pocket and putting it into another (moving away from the marginal equilibrium) decreases overall returns. Clearly, stop when even the marginal return at the origin of an activity cannot contribute as much as its more lucrative fellows.

It is characteristic of such solutions that some activities receive no effort. For example, in some air defense problems, targets of very low value get no defense allocation.

A considered or experienced guess can frequently come within 5 percent of the calculated optimum. This is again typical of these problems. But (1) you never know how close you are to the optimum, (2) the improvement being interest on an investment, making many investments adds up, and (3) if, for reasons external to the model, certain allocations to certain categories are specified, you will know what penalty is paid.

Fig. 13.1—A return function

Fig. 13.2—Solution algorithm

Example. Based on estimated initial position and drift, a damaged ship may be in one of four search sectors with estimated probabilities 0.5, 0.3, 0.15, 0.05. Because of weather and sea conditions, the conditional probabilities that one search sortie will detect the target in these sectors are 0.1, 0.3, 0.4, 0.2, respectively. Find the best allocation of 20 sorties to maximize the detection probability.

We have

| <u>Sector</u> | <u>s</u> | <u>p</u> | <u>m</u> | <u>sm</u> | <u>Reindex</u> |
|---------------|----------|----------|----------|-----------|----------------|
| 1 | 0.5 | 0.1 | 0.105 | 0.053 | 3 |
| 2 | 0.3 | 0.3 | 0.357 | 0.107 | 1 |
| 3 | 0.15 | 0.4 | 0.511 | 0.077 | 2 |
| 4 | 0.05 | 0.2 | 0.223 | 0.011 | 4 |

The program yields $x_1^* = 5.4$, $x_2^* = 3.1$, $x_3^* = 11.5$, $x_4^* = 0$. The sum is 20 as it must be. The detection probability is 0.73. Figure 13.3 shows the Q functions and the solution points and illustrates the algorithm. But it indicates also that the schematic of Fig. 13.2 is not the general case. That is, it is not necessarily true that $x_1^* \geq x_2^* \geq x_3^* \dots$

13.4. PROGRAM NOTES

Although short and simple in structure, the program has several elements of interest.

(1) LBL A loads $1/m_i$ using indirect storing. LBL B loads $S_i m_i$ into protected secondary storage, also using indirect storing. But care must be taken to indicate whether f P \leftrightarrow S puts the memory in the primary or secondary storage mode. This is particularly important when exiting from a loop in the middle of a label.

(2) LBL 1 determines the successive x_i^* (Eq. (8)) by f ISZ up to ℓ .

(3) LBL 2 then determines R^* by forming the sum (Eq. (9)) in reverse order from ℓ down to 1. f DSZ provides the exit by skipping on zero.

PART III

COST PROGRAMS

14. LOG-LINEAR CUMULATIVE AVERAGE AND UNIT COSTING

14.1. REFERENCES

- a. H. E. Boren, Jr. and H. G. Campbell, *Learning Curve Tables*, The Rand Corporation, RM-6191-PR, April 1970 (3 vols.).
- b. R. W. Hamming, *Numerical Methods for Scientists and Engineers*, McGraw-Hill, New York, 1962.

14.2. DISCUSSION

Learning curve theory assumes that each time the total quantity of items produced doubles, the cost per item is reduced to a constant percentage of the previous cost. The relationship is given by the power or log-linear relation

$$y = ax^b,$$

where x is the cumulative production quantity. If y is the average cost of the first x units, we have the cumulative average learning curve. If y is the cost of the x th unit, we have the unit learning curve.

For plotting purposes, the midpoint x_m , corresponding to the lot average cost, is to be determined.

14.3. EQUATIONS

If S is the fraction to which cost decreases (the learning curve percentage) when the quantity is doubled, the slope of the learning curve is

$$b = \ln S / \ln 2. \quad (1)$$

Then, with a the cost of the first unit,

$$y_c = ax^b \quad (2)$$

is the average cost of the first x units, and the total cost for the first x units is

$$T = xy_c = ax^{b+1} . \quad (3)$$

The unit cost at the x th unit is

$$y_u = a \left[x^{b+1} - (x-1)^{b+1} \right] . \quad (4)$$

Let (x_m, y_m) be the midpoint for the first lot of n units. Then $y_m = y_c = an^b$, and using (4), x_m is the solution of the equation

$$x_m^{b+1} - (x_m - 1)^{b+1} - n^b = 0 . \quad (5)$$

The above equations apply to the log-linear cumulative case.

For the log-linear unit curve, the unit cost at the x th unit is

$$y_u = ax^b \quad (6)$$

and the cumulative average cost for the first n units is

$$y_c = \frac{a}{n} \sum_{x=1}^n x^b , \quad (7)$$

since the total cost is

$$T = a \sum_{x=1}^n x^b . \quad (8)$$

The midpoint (x_m, y_m) is determined by

$$y_m = y_c , \quad x_m = (y_m/a)^{1/b} . \quad (9)$$

The only programming problems are posed by Eqs. (5) and (8).

In applying Newton's method to (5), a good first estimate is needed for x_m . We have

$$\begin{aligned} f(x) &= x^{b+1} - (x-1)^{b+1} - n^b \\ &= x^{b+1} - x^{b+1} (1 - 1/x)^{b+1} - n^b, \end{aligned}$$

and using the first two terms in the expansion of $(1 - 1/x)^{b+1}$, the first estimate for x is

$$x_0 = n/(b+1)^{1/b}, \quad (10)$$

which is very close for large n .

To get an excellent approximation for the sum in Eqs. (7) and (8), use the Gregory formula (Ref. a, p. 158):

$$\begin{aligned} \int_0^n f(x) dx &= \frac{1}{2} (f_0 + f_n) + \sum_{i=1}^{n-1} f_i + \frac{1}{12} (\Delta f_0 - \Delta f_{n-1}) \\ &\quad - \frac{1}{24} (\Delta^2 f_0 + \Delta^2 f_{n-2}) + \dots \end{aligned}$$

Because x^b is integrable, the formula can be applied in the backward direction to get the sum. Since x^b is steep for small x , we start the sum at $x = 4$. (Hamming calls this "low cunning.") We have

$$\begin{aligned} \sum_{x=1}^n x^b &\doteq 1 + 2^b + 3^b + \int_3^{n+1} x^b dx - \frac{1}{2} [3^b + (n+1)^b] \\ &\quad - \frac{1}{12} [4^b - 3^b - (n+1)^b + n^b] \\ &\quad + \frac{1}{24} [5^b - 2 \cdot 4^b + 3^b + (n+1)^b - 2 \cdot n^b + (n-1)^b], \end{aligned}$$

yielding the rather inelegant result

$$\sum_{x=1}^n x^b = 1 + 2^b + \left[\frac{5}{8} - \frac{3}{b+1} \right] 3^b - \frac{1}{6} 4^b + \frac{1}{24} 5^b$$

$$+ \frac{1}{24} (n-1)^b - \frac{1}{6} n^b + \left[\frac{n+1}{b+1} - \frac{3}{8} \right] (n+1)^b. \quad (11)$$

14.4. PROGRAM NOTES

1. In finding a first approximation to the root of Eq. (5) by expression (10), a value less than 1 arises for small n (<5). This would lead to an Error signal because of $(x-1)^{b+1}$. LBL 2 provides a starting value of 1.01 to avoid this.

2. For small values of n (<5), get $\int x^b$ by manual calculation (not programmed).

3. The programming done here involved experimenting with the relatively uncommon second-order Newton method for the root of $f(x) = 0$. The formula^{*} is

$$x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)} \left[1 + \frac{f(x_n) f''(x_n)}{2(f'(x_n))^2} \right],$$

compared with the first-order method's

$$x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)}.$$

Convergence to a given accuracy is somewhat faster (20 percent in running time) but at additional programming cost to get $f''(x)$. The first-order method is used, employing DSP 2, f RND, to get two-decimal-place accuracy.

4. Obviously, $a = 1$ in programming, since a is simply a multiplier.

^{*} There is a typographical error in this formula as given on p. 82 of Ref. a.

15. TIME-PHASED PROCUREMENT COSTING

15.1. REFERENCES

None.

15.2. DISCUSSION

The costing approach of this section is a hitherto undocumented model owing to H. G. Massey of The Rand Corporation. For definiteness, the model will be explained in terms of aircraft procurement, although it applies equally to the procurement of any system with any number of components. The initial batch of test articles is not priced, it being assumed that they are funded from another account. But the average prices of the batch's components provide the costs of initial articles for learning curve calculations. Overruns and inflation are not included. The model determines, by fiscal year, New Obligational Authority (NOA) required to meet the production/delivery schedule.

15.3. EQUATIONS

Specify that two required sequences of possessed aircraft (S_n, T_n), $n = 1, \dots, N$, are to be in the fleet at the end of year n , where S_n are squadron or UE aircraft and T_n are training aircraft.

If A and B are flying hours per year per aircraft (FH/Y), for squadron and training aircraft, the *cumulative* fleet flying hours through year n are approximately

$$H_n = \sum_{i=1}^n [AS_i + BT_i] . \quad (1)$$

The *cumulative* fleet attrition is given by

$$a_n = C \cdot H_n^d . \quad (2)$$

A fraction λ of the fleet is assigned to command support (pipeline). With allowance for these two factors, the *cumulative* number of aircraft to be procured through year n is

$$Q_n = (1 + \lambda) P_n + a_n . \quad (3)$$

If the fleet is to be kept in a steady-state condition (S_N, T_N) for M more years, aircraft will be delivered in year $N + 1$ to meet the attrition requirements of these M years. Hence H_{N+1} and a_{N+1} will be calculated to determine this final buy.

An aircraft has three major components: engines, airframe, and avionics. There is a cumulative buy program for each component, allowing for lead times and learning curve effects. Cumulative average costing is most convenient (see Sec. 14).

Take engines first. The procurement parameters can be written as the string of numbers

$$(a_1, p_{11}, x_{11}, p_{12}, x_{12}, p_{13}, t_1, \mu_1) ,$$

where the first subscript refers to component 1 (engines) and a_1 is the cost of the first article, p_{11} is the learning curve percentage (or rather fraction) up to article number x_{11} , p_{12} is the learning curve percentage for articles $x_{11} + 1$ up to x_{12} , and p_{13} is the subsequent percentage. Of course, a learning curve may have only one or two segments. The lead time in months is t_1 , so that an engine takes t_1 months from start of fabrication to delivery to the fleet as part of a complete aircraft. (Mating of engines and avionics with the airframe is taken to be part of the airframe lead time and cost.) The number of engines required per aircraft is μ_1 , allowing for multi-engine models and spares. With these production parameters:

Up to x_{11} the cumulative average total cost for x articles is

$$a_1 x^{b_{11}+1} , \quad (4)$$

where $b_{11} = \ln p_{11} / \ln 2$.

From $x_{11} + 1$ to x_{12} , the cumulative total cost is

$$a_1 \cdot x_{11}^{b_{11}-b_{12}} \cdot x^{b_{12}+1}, \quad (5)$$

and above $x_{12} + 1$,

$$a_1 \cdot x_{11}^{b_{11}-b_{12}} \cdot x_{12}^{b_{12}-b_{13}} \cdot x^{b_{13}+1}. \quad (6)$$

These expressions are verified by putting $x = x_{11}$ in (5) and $x = x_{12}$ in (6). These expressions define a *cumulative* cost function $c_1(x)$ for all articles numbered 1 through x .

Next express t_1 in years and write

$$t_1 = \text{INT}(t_1) + \text{FRAC}(t_1).$$

Thus a 26-month lead time is $2.167 = 2 + 0.167$. Then fabrication starts at $-t_1$, but during the fiscal year $-\text{INT}(t_1)$, only $\mu Q_1 \text{ FRAC}(t_1)$ articles will be started, requiring NOA of

$$C_1(\mu Q_1 \text{ FRAC}(t_1)).$$

To the end of the next FY, $-\text{INT}(t_1) + 1$, the *cumulative* number of engines started is

$$\mu Q_1 + \mu(Q_2 - Q_1) \text{ FRAC}(t_1), \quad (7)$$

and NOA for that FY is

$$C_1(\mu Q_1 + \mu(Q_2 - Q_1) \text{ FRAC}(t_1)). \quad (8)$$

By example, if $t_1 = 26$ months, $Q_1 = 16.91$, $Q_2 = 35.17$,

Note that deliveries to the fleet are made at a uniform rate during a year. So that formula (7) will apply for the first year and the last year, store $Q_0 = 0$ and store Q_{N+1} as Q_{N+2} . Then, for the last FY, we will have the correct cumulative total Q_{N+1} .

The above procedure applies equally to the remaining two components. The program then generates the *cumulative* NOA component by component. The user then adds vertically by FY, and takes differences horizontally to get the final NOA by FY that the procurement program would demand.

The model well illustrates the simplicity resulting when cumulative average costing is used rather than unit costing.

15.4. PROGRAM NOTES

1. LBL A uses indirect addressing and simple looping to produce the cumulative flying hours H_i .
2. LBL B computes required cumulative aircraft Q_i and puts these in the primary storage originally occupied by the squadron and training aircraft of the original schedule.
3. The GTO E of line 074 will lead to the storage of Q_{N+1} in Q_{N+2} also (see above for reason).
4. LBL C calculates the coefficients required for a segmented learning curve.
5. LBL 6 calculates the successive cumulative number of articles produced and NOA required as the fiscal years are incremented.
6. "Packed" storage is used extensively. Thus, $S_2 = 24$ and $T_2 = 6$ are stored in Register 2 as 24.06. Then S_2 is retrieved by 'f INT' and T_2 by 'g FRAC, EEX 2, X'. This storage device is useful

when storage space is at a premium, but care must be taken in fixing the number of places after the decimal point. Thus storing 24.6 instead of 24.06 would cause the program to produce 60 for T_2 instead of 6. You also pay for "packing" in the coin of program steps.

7. To hold the program to 224 steps, the user is asked to do considerable but simple inputting, such as: Given a lead time t of 26 months, key in 26 and then 'ENTER, 12, \div , STO 6'.

8. For lack of storage space, the user records output as produced and does some final additions and subtractions to get the NOA by fiscal year.

Example. The required buildup schedule is:

| End of FY | 1 | 2 | 3 | 4 | 5 | 6 |
|---------------|----|----|----|----|-----|-----|
| Squadron acft | 12 | 24 | 48 | 84 | 108 | 108 |
| Training acft | 3 | 6 | 12 | 21 | 27 | 27 |

The steady-state fleet is to be reached at the end of year 5. This will be kept constant through year 10. $FH/Y = 240$ for squadron acft and 720 for training acft. The cumulative attrition coefficient is 0.00015 and the exponent is 1.05. The command support factor is 5 percent. The engine learning curve has three segments, and the parameters for this component are

$$a_1 = 10, p_{11} = 0.9, x_{11} = 60, p_{12} = 0.8, x_{12} = 110, \\ p_{13} = 0.6, t_1 = 26, \mu_1 = 2.5 .$$

For the airframe (two segments):

$$a_2 = 25, p_{21} = 0.85, x_{21} = 30, p_{22} = 0.75, t_2 = 20, \mu_2 = 1 .$$

For avionics (one segment):

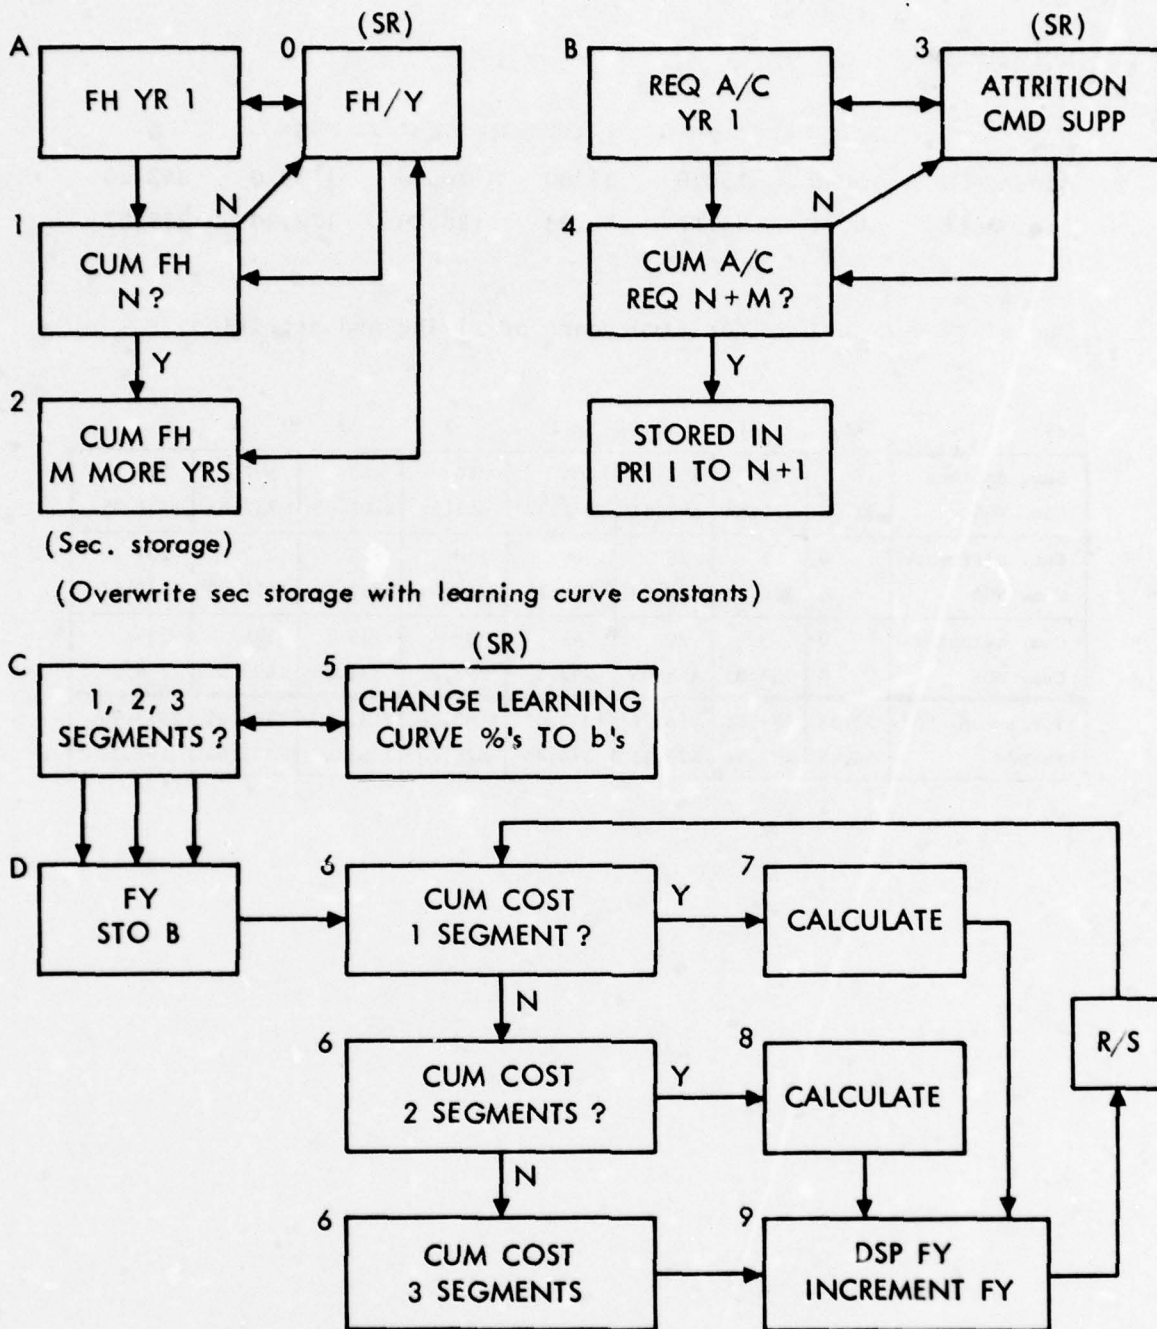

$$a_3 = 30, p_{31} = 0.75, t_3 = 14, \mu_3 = 1 .$$

Calculation

| FY | 1 | 2 | 3 | 4 | 5 | 6 |
|-----------|-------|-------|-------|--------|--------|--------|
| Accum. FH | 5040 | 15120 | 35280 | 70560 | 115920 | 342720 |
| Req. acft | 16.91 | 35.17 | 71.93 | 128.75 | 172.90 | 238.97 |

The sixth year allows for five years of flying and attrition.

16. COST/BENEFIT STREAMS

16.1. REFERENCES

None.

16.2. DISCUSSION

The model of this section is also due to H. G. Massey of The Rand Corporation. It deals with decisions to spend money now as opposed to later during the life cycle of a weapon system. That is, should engineering development monies be spent now with the expectation that future operating and support costs will be lower? The planner must decide, for example, whether to install engine diagnostic equipment now, assuming that future maintenance will otherwise be less efficient and therefore more costly. The model quantifies such decision problems, using as a yardstick the present value of a discounted stream of expenditures and benefits, both of which are expressed in constant dollars (no allowance for inflation).

A simple example will illustrate. Suppose we assume that \$10M spent now will lead to operating and support (O&S) costs of \$20M 8 years from now; if no money is spent now, these future costs will be \$40M. Let the discount rate be 10 percent, as currently mandated by the Department of Defense. If the \$10M were invested at 10 percent compounded interest for 8 years, it would yield \$21.4M. Consequently, we would save \$1.4M by *not* improving the system now. But if the rate were 5 percent, we would *lose* \$5.2M by not improving the system now. It follows that the rate mandated or assumed has a controlling impact on the decision.

With respect to estimating the future costs (\$20M and \$40M above), one other crucial point must be made. Suppose the system in question is a fleet of aircraft of a given type. Then we must keep the operational capability constant in the two cases. That is, the O&S costs must be assessed in both cases to produce the same in-commission rate or other measure of operational capability for the fleet.

16.3. EQUATIONS

Set a time horizon of N future fiscal years, the expected life of the weapon system. Let C_i be the costs of the proposed near-term improvements for years $1, \dots, N$. Let B_i be the assessed *incremented* O&S *savings* given the stream C_i . Then the discounted present value of the benefit/cost stream at a rate r is

$$P(r) = \sum_{i=1}^N (B_i - C_i)(1+r)^{-i+1}, \quad (1)$$

since by convention present values are stated for fiscal year 1.

The "breakeven" year j is defined as the first j for which

$$\sum_{i=1}^j (B_i - C_i)(1+r)^{-i+1} > 0, \quad (2)$$

if $P(r) > 0$.

The "internal rate of return" is that r^* for which

$$P(r^*) = 0. \quad (3)$$

If the actual rate r is greater than r^* , then $P(r) < 0$, because $(1+r)^{-i+1} < (1+r^*)^{-i+1}$. In this case, the near-term improvement investment would not be made.

The value r^* is found by Newton's method. We have, using $D_i = B_i - C_i$,

$$\begin{aligned} P'(r) &= \sum_{i=1}^N (1-i) \cdot D_i \cdot (1+r)^{-i} \\ &= \frac{1}{1+r} \left[P(r) - \sum_{i=1}^N i \cdot D_i \cdot (1+r)^{-i+1} \right], \end{aligned} \quad (4)$$

which is written in this form to simplify the programming. Finally

$$1 + r_n = 1 + r_{n-1} - \frac{(1 + r_{n-1}) \cdot P(r_{n-1})}{P(r_{n-1}) - \sum_{i=1}^N D_i \cdot (1 + r)^{-i+1}} \quad (5)$$

16.4. PROGRAM NOTES

(1) This program uses indirect addressing in a natural and straightforward fashion. The successive D_i 's are stored in registers 1, ..., 19 (19 years is the maximum for this program). Looping by f ISZ is then simple.

(2) To get the breakeven year, we want to test for a change of sign in

$$P(j, r) = \sum_{i=1}^j D_i (1 + r)^{-i+1}$$

as this partial sum crosses the time axis. A simple procedure is to test the ratios $P(j+1, r)/P(j, r)$ to see when, if at all, the ratio is *negative*.

(3) In using Newton's method, a simple first-guess at the root is $r = 0$. But $1 + r$ or 1 is then stored in B. If any iteration produces $1 + r < 1$, stop. In this case there is no internal rate of return.

PART IV

MATHEMATICAL FUNCTIONS AND ALGORITHMS

17. THE NORMAL FUNCTION AND ITS INVERSE

17.1. REFERENCES

None.

17.2. DISCUSSION

This program is frequently used in conjunction with others, such as the Q function (Program 18). Extensive application of the error function is made in *Hewlett Packard HP-65 Programs for Evaluating Effectiveness of Field Artillery Weapons*, prepared for the Joint Technical Coordinating Group for Munitions Effectiveness (Surface-to-Surface) by Booz-Allen Applied Research, Shalimar, Florida, September 1975.

17.3. EQUATIONS

The normal distribution, or function, is

$$F(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^x \exp(-t^2/2) dt, \quad (1)$$

where x is in units of σ . An early approximation, due to J. D. Williams, is

$$F_0(x) = \frac{1 + [1 - \exp\{-2x^2/\pi\}]^{1/2}}{2}, \quad x \geq 0, \quad (2)$$

which has a maximum error of about 0.002. R. N. Snow replaces the curly brackets in (2) by

$$-2x^2 \left(\frac{1}{\pi} - \frac{x^2}{x^4 + 230} \right)$$

and obtains an accuracy better than 0.0001.

PRECEDING PAGE BLANK

A first approximation to the inverse is obtained by solving (2) for x ,

$$x_0 = \left[-\frac{\pi \ln \{1 - (2F_0 - 1)^2\}}{2} \right]^{1/2} \quad (3)$$

For greater accuracy, x_0 is used in solving the equation $F(x) - y = 0$ by Newton's method, which is appropriate since the derivative is simple,

$$F'(x) = \frac{1}{\sqrt{2\pi}} \exp(-x^2/2) .$$

The error function is

$$\text{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt , \quad \text{and} \quad (4)$$

$$\text{erf}(x) = 2 \cdot F(\sqrt{2} \cdot x) - 1 . \quad (5)$$

Given a value E to find the corresponding x , use this program with $F = 1/2 [1 + E]$ and divide the resulting value by $\sqrt{2}$.

Example 1. Find $\text{erf}(0.5)$.

Key in $1/\sqrt{2}$, PRESS A, then 2, x , 1 - .

Answer is 0.5206.

Example 2. Find x for $\text{erf}(x) = 0.5206$.

Key in $F = (1 + 0.5206)/2$, PRESS B, PRESS C, $\sqrt{2}$, \div .

Answer is 0.50.

17.4. PROGRAM NOTES

None.

18.2. DISCUSSION

The Q function

$$Q(r, R) = \int_R^{\infty} u \exp \left\{ -\frac{r^2 + u^2}{2} \right\} \cdot I_0(ru) du \quad (1)$$

is basic in radar detection theory. It is expressible in Lommel functions of the first kind (Ref. a), but is not integrable in closed form.

The Q function's more common application is perhaps in offset bombing calculations. For a circular normal distribution $(0, \sigma)$, a weapon radius R (in units of σ), and a point target at a distance r (in units of σ) from the origin (the aiming point), the probability of coverage is simply $P(R, r) = 1 - Q(r, R)$. If CEP in feet is used and r' , R' are in feet,

$$r = r' \frac{\sqrt{2 \ln 2}}{\text{CEP}}, \quad R = R' \frac{\sqrt{2 \ln 2}}{\text{CEP}},$$

$$\sqrt{2 \ln 2} = 1.17741.$$

The damage probability program (Sec. 9) can be used to get weapon radius, and this program is then employed to find collateral damage to other point targets.

18.3. EQUATIONS

The Bessel function $I_0(x)$ is given by

$$I_0(x) = \sum_{n=0}^{\infty} \left(\frac{x}{2}\right)^{2n} / (n!)^2 . \quad (2)$$

Put (2) in (1) and interchange the order of summation and integration to get

$$P(R, r) = 1 - Q(r, R) = \sum_{n=0}^{\infty} k_n(r^2/2) K_n(R^2/2) , \quad (3)$$

where

$$k_n(y) = x^n e^{-y} / n! \quad (4)$$

$$K_n(x) = \int_0^x \frac{u^n e^{-u}}{n!} du = \frac{\Gamma_{n+1}(x)}{n!} ,$$

and Γ_{n+1} is the incomplete gamma function.

The recursion relations for k_n and K_n are

$$\begin{aligned} k_0(y) &= e^{-y} \\ k_n(y) &= \frac{y}{n} k_{n-1}(y) , \quad n > 0 \\ K_0(x) &= 1 - e^{-x} \end{aligned} \quad (5)$$

$$K_n(x) = K_{n-1}(x) - k_n(x) , \quad n > 0 ,$$

After N iterations,

$$P(R, r) = \sum_{n=1}^{N-1} k_n K_n + R(N) ,$$

where the remainder

$$R(N) = \sum_{n=N}^{\infty} k_n K_n . \quad (6)$$

Reference c shows, for $N > rR/\sqrt{2}$, that

$$R(N+1) \leq k_N(r^2/2) K_N(R^2/2) . \quad (7)$$

Let $N_0 = rR/\sqrt{2}$ and let Δ be the desired accuracy. Then the iteration can be terminated at $n = N$, if

$$N > N_0 , \quad k_N(r^2/2) K_N(R^2/2) \leq \Delta . \quad (8)$$

If r and R are small, the convergence is rapid. But as r and R increase, the number of terms required--and thus computation time--become excessive.

However, for $r, R \geq 5$, Ref. d provides an excellent approximation in terms of the cumulative Gaussian function

$$P(R, r) = \frac{1}{\sqrt{2\pi}} \int_{Z_0}^{\infty} e^{-u^2/2} du + E(Z_0) , \quad (9)$$

where

$$Z_0 = (R - r)(1 - 1/4r^2) - 1/2r . \quad (10)$$

The approximation is improved by adding two more terms to (10), taking

$$Z_1 = (R - r)(1 - 1/4r^2) - 1/2r^3 - 1/48r^3 - (R - r)^2/10r^3. \quad (11)$$

Then the error $E(Z_1) \leq 0.0005$ for $r \geq 4.25$. It can also be shown that for

$$R \geq 2.45 + \frac{1}{r - 1.7}, \quad (12)$$

$$E(Z_1) \leq 0.0005.$$

The regions of interest for the $P(R, r)$ calculation are then shown in Fig. 18.1. For region A, use the iteration method, Eqs. (3) and (8). The maximum number of iterations required to obtain an error $\Delta < 0.0005$ is 10. For region B, use the approximation (11) in (9), with an execution time of 7 sec. In general, the regions above $R - r = -2.8$ and below $R - r = 2.8$ are without interest. However, even in these regions, the approximation method may be used.

18.4. PROGRAM NOTES

1. For an accuracy $\Delta \leq 0.0005$, enter R , r , and Δ and press B. The program will choose the better method to compute $P(R, r)$. "Better" is defined as entailing the least computer time to obtain at least accuracy Δ .

2. For an accuracy Δ better than 0.005, again enter R , r , and Δ but press A.

19.2. DISCUSSION

The 3-activity linear programming problem may be formulated:

find $x_1 \geq 0$, $x_2 \geq 0$, $x_3 \geq 0$ satisfying

$$a_{11} x_1 + a_{12} x_2 + a_{13} x_3 \leq b_1$$

$$a_{21} x_1 + a_{22} x_2 + a_{23} x_3 \leq b_2$$

$$a_{31} x_1 + a_{32} x_2 + a_{33} x_3 \leq b_3$$

to maximize

$$M = c_1 x_1 + c_2 x_2 + c_3 x_3 .$$

The recipe for solving this problem by the pivot method is very simple, although the result of deep and extensive analysis. Set up Tableau 1:

| x_1 | x_2 | x_3 | | |
|----------|----------|----------|-------|-------|
| a_{11} | a_{12} | a_{13} | b_1 | u_1 |
| a_{21} | a_{22} | a_{23} | b_2 | u_2 |
| a_{31} | a_{32} | a_{33} | b_3 | u_3 |
| $-c_1$ | $-c_2$ | $-c_3$ | 0 | M |

TABLEAU 1

1. The pivot *column* corresponds to the most *negative* of $-c_1$, $-c_2$, $-c_3$. Say this is $-c_2$.
2. The pivot *row* is found by finding

$$b_1/a_{12}, \quad b_2/a_{22}, \quad b_3/a_{32}$$

for only those b 's that are *positive*, and then selecting the minimum. Say this is b_3/a_{32} . Then the pivot is a_{32} .

3. Replace the pivot by its reciprocal, and divide all other entries in the pivot's column by the negative of the pivot.
4. For an entry *other* than those in the pivot's row and column, add to that entry the product of the entry in the same column to the left or right of the pivot in *its* row and the entry in the (new) pivot's column to the left or right of the entry in *its* row.
5. Now modify the pivot's row by dividing all entries other than the pivot by the pivot.
6. Interchange x_2 and u_3 .

These operations produce the new Tableau 2:

| x_1 | u_3 | x_3 | | |
|------------------------------------|------------------|------------------------------------|------------------------------|-------|
| $a_{11} + a_{31} (-a_{12}/a_{32})$ | $-a_{12}/a_{32}$ | $a_{13} + a_{33} (-a_{12}/a_{32})$ | $b_1 + b_3 (-a_{12}/a_{32})$ | u_1 |
| $a_{21} + a_{31} (-a_{22}/a_{32})$ | $-a_{22}/a_{32}$ | $a_{23} + a_{33} (-a_{22}/a_{32})$ | $b_2 + b_3 (-a_{22}/a_{32})$ | u_2 |
| a_{21}/a_{32} | $1/a_{32}$ | a_{33}/a_{32} | b_3/a_{32} | x_2 |
| $-c_1 + a_{31} (c_2/a_{32})$ | c_2/a_{32} | $-c_3 + a_{33} (c_2/a_{32})$ | $0 + b_3 (c_2/a_{32})$ | M |

TABLEAU 2

In the numerical example below, the initial pivot is a_{23} (not a_{32} as above).

Example (Ref. b, Sec. 5)

| x_1 | x_2 | x_3 | | |
|-------|-------|-------|-----|-------|
| 1 | 1 | 1 | 100 | u_1 |
| 3 | 2 | (4) | 210 | u_2 |
| 3 | 2 | 0 | 150 | u_3 |
| -5 | -4 | -6 | 0 | M |

(Tableau 1)

| x_1 | x_2 | u_2 | | |
|-------|-------|-------|-------|-------|
| 1/4 | 1/2 | -1/4 | 47.5 | u_1 |
| 3/4 | 1/2 | 1/4 | 52.5 | x_3 |
| 3 | (2) | 0 | 150.0 | u_3 |
| -1/2 | -1 | 3/2 | 315.0 | M |

(Tableau 2)

7. Repeat the above process until all entries in the bottom row are *nonnegative*. In the rightmost column read the optimal x 's and maximum M . Any u left in that column indicates that the corresponding x is 0.

Continuing the example,

| x_1 | u_3 | u_2 | | |
|-------|-------|-------|-----|-------|
| -1/2 | -1/4 | -1/4 | 10 | u_1 |
| 0 | -1/4 | 1/4 | 15 | x_3 |
| 3/2 | 1/2 | 0 | 75 | x_2 |
| 1 | 1/2 | 3/2 | 390 | M |

$$x_1 = 0, x_2 = 75, x_3 = 15, M = 390 \text{ (Answer)}$$

(Tableau 3)

The previous example in equation form is:

find $x_1 \geq 0, x_2 \geq 0, x_3 \geq 0$ subject to

$$x_1 + x_2 + x_3 \leq 100$$

$$3x_1 + 2x_2 + 4x_3 \leq 210$$

$$3x_1 + 2x_2 \leq 150$$

$$\text{to maximize } M = 5x_1 + 4x_2 + 6x_3.$$

Suppose the problem were:

find $x_1 \geq 0, x_2 \geq 0, x_3 \geq 0$ subject to

$$x_1 + x_2 + x_3 \geq 100$$

$$3x_1 + 2x_2 + 4x_3 \geq 210$$

$$3x_1 + 2x_2 \geq 150$$

$$\text{to minimize } m = 5x_1 + 4x_2 + 6x_3.$$

We set up the *dual* problem (the pattern should be clear):

find $y_1 \geq 0, y_2 \geq 0, y_3 \geq 0$ subject to

$$y_1 + 3y_2 + 3y_3 \leq 5$$

$$y_1 + 2y_2 + 2y_3 \leq 4$$

$$y_1 + 4y_2 \leq 6$$

to maximize $M = 100y_1 + 210y_2 + 150y_3$, and solve this problem by the previous method. The values for x variables are now read off on the bottom row under the interchanged u 's with the same subscript.

The relation of the duals is clarified by using the program to solve 3×3 matrix games. The procedure is readily understood by following through a specific example.

BLUE is the maximizing player, RED his minimizing opponent. It is desirable to add a constant to all entries in the payoff matrix to make all entries positive if necessary.

This increases the value of the original game by that constant but does not change the proportions in which the strategies are played. The new example is

| | | RED | | |
|------|-------|-------|-------|-------|
| | | r_1 | r_2 | r_3 |
| BLUE | b_1 | 2 | 6 | 0 |
| | b_2 | 5 | 3 | 6 |
| | b_3 | 5 | 4 | 3 |

where b_i (r_j) is the probability BLUE (RED) will choose course of action or strategy i (j). Then

$$1 \geq b_i \geq 0, 1 \geq r_j \geq 0, b_1 + b_2 + b_3 = 1, r_1 + r_2 + r_3 = 1.$$

Look at matters from RED's point of view. Against each of BLUE's pure strategies, RED must expect to pay BLUE

$$2r_1 + 6r_2, 5r_1 + 3r_2 + 6r_3, 5r_1 + 4r_2 + 3r_3 .$$

Let μ (unknown) be the greatest of these three. Then putting $y_i = r_i/\mu$,

$$2y_1 + 6y_2 \leq 1, 5y_1 + 3y_2 + 6y_3 \leq 1, 5y_1 + 4y_2 + 3y_3 \leq 1 ,$$

and RED wants to minimize μ by maximizing $M = 1/\mu$,

$$M = y_1 + y_2 + y_3 .$$

This is the standard linear programming problem with the right-upper border all +1's and the left lower border all -1's. The first tableau is:

| y_1 | y_2 | y_3 | | |
|-------|-------|-------|---|-------|
| 2 | 6 | 0 | 1 | v_1 |
| 5 | 3 | 6 | 1 | v_2 |
| 5 | 4 | 3 | 1 | v_3 |
| -1 | -1 | -1 | 0 | M |

Any column could be the first pivot column. We choose the circled number as the pivot because $1/6 < 1/5$ (a variation on step (2) above).

The second tableau (by the program) is:

| y_1 | v_1 | y_3 | | |
|-------|-------|-------|-----|-------|
| 2 | .17 | 0 | .17 | y_2 |
| 4 | -.50 | 6 | .50 | v_2 |
| 3.67 | -.67 | 3 | .33 | v_3 |
| -.67 | .17 | -1 | .17 | M |

The third tableau is:

| y_1 | v_1 | v_2 | | |
|-------|-------|-------|-----------|-------|
| 2 | .17 | 0 | .17(1/6) | y_2 |
| .67 | -.08 | .17 | .08(1/12) | y_3 |
| 1.67 | -.42 | -.50 | .08(1/12) | v_1 |
| 0 | .08 | .17 | .25(1/4) | M |

The value of the game is $1/8 = .125$. Since $x_1 = 2$, $x_2 = 0$, $x_3 = 1/2$, $x_4 = 1/2$. By the duality theorem of linear programming, we immediately read off Ed's set of optimal action strategies from the final row. The second column is headed by v_1 with value $-.42$, so that $y_1 = 1/2$, $y_2 = 1/2$. Similarly, $y_3 = 1/2$ and $y_4 = 0$. Thus we recover the strategy in p. 87 of Ed. p. 87 has been added to our version of the game matrix. The value then is 0 rather than $1/8$.

Ed's strategy:

Ed's strategy:

Ed's strategy:

The optimal strategy for Ed is to choose $y_1 = 1/2$, $y_2 = 1/2$, $y_3 = 1/2$, $y_4 = 0$. The value of the game is $1/8$.

it is given in the high-level language appropriate to our minds, but only with care and time do we avoid errors.

The HP-67 understands only a relatively low-level language even though it is quite advanced over early coding in machine language. So what we see without effort (the *Gestalt*) requires many steps of programming.

2. The programming problem is compounded in difficulty because the HP-67 cannot work with the double indices of matrix elements. We must "linearize" the matrix and devise an "address arithmetic" for this problem, and then exploit the indirect addressing capability of the I-register.

Consider item (4) of the recipe. Overlay the linear programming matrix with the matrix of register addresses of entries:

| | | | |
|----|----|-------|-------|
| 0 | 1 | 2(y) | 3(e) |
| 4 | 5 | 6 | 7 |
| 8 | 9 | 10(p) | 11(x) |
| 12 | 13 | 14 | 15 |

where 11, for example, is secondary storage register 11, which is indirect addressing to 11. The content of this register is b_{11} (see Table 1). Denote the contents of a register by (x) , where x is the register's name. Suppose the price $y = 100$, the entry to be subtracted is 12 so $x = 12$, but $x = 11$ and $y = 12$. Note that x is the 11 value and y is the 12 value after that 12 has been converted to x . Then the 11 value $x' = x + y$ is $12 + 100 = 112 = 12$.

For subtraction, then, having $x = 12$, $y = 12$ and so on, let $x = x + 12$ (12 = 12) and so on. Thus $x = x + 12$, $y = 12$.

It is important that operations involving x be on values after subtracting y to the value x of x .

3. The program is written which reads in the appropriate values. The program is an HP-67 program, convertible to the program of the computer with the proper modifications.

4. Items (1) and (2) of the recipe are not carried out by this program. They can be programmed, but only at the cost of an additional program card and thus of time. And in this case a man can find the pivot faster than the machine can if he has the matrix in front of him.

The philosophical argument is that the HP-67 and the user are engaged in a cooperative one-shot (or few-shot) enterprise, rather than bulk or production computing. Each partner should contribute what he can do better and quicker.

5. Running time for each iteration is 47 sec, exclusive of the final display (f -x-) of the new tableau for manual recording.

20. FOURTH-ORDER DIFFERENTIAL EQUATIONS

20.1. REFERENCE

- a. R. W. Hamming, *Numerical Methods for Scientists and Engineers*, McGraw-Hill, New York, 1962.

20.2. DISCUSSION

Systems of four first-order (frequently nonlinear) differential equations, sometimes in the guise of two second-order equations, occur more commonly than one would think: The basic beam deflection equation is of the fourth order; chemical kinetic systems with four (or more) equations are common; reentry trajectories are specified by two second-order equations (see Program 4); Lanchester equations with two force components for each side and with variable coefficients occur; problems in optimal control theory and in differential game theory lead to such systems.

Since the HP-67 has a limited number of storage registers (26) and of program steps (224), and since program space is needed to define the functions of the system, we seek an alternative to the rather complex Runge-Kutta "standard" formulas, an alternative that is miserly of program space and yet has good accuracy for relatively large time intervals--that is, *good relative stability*, defined as the rate of growth of the error relative to the growth of the solution.

Moreover, programming must fully exploit the indirect control afforded by the powerful I-register. That is, the number in the I-register can be the *address* of a storage register or the *name* of a label (subroutine). Then the instruction STO (i) or RCL (i) or GTO (i) moves X-register data to the right register or recalls data from the desired register or sends the program to the right place. Hence, in conjunction with incrementing and decrementing the I-register, serial treatment of all four equations can be accomplished with the same economical set of processing instructions.

The final programming problem is to move data around, like freight cars in a marshalling yard, so that storage spaces are freed just in time to make space for a new claimant.

20.3. EQUATIONS

Section 14.3 of Ref. a describes a simple predictor-corrector approach for first-order equations that seems to have promise and is readily extended to a system of equations.

Consider the equation

$$dx/dt = X(x,t), \quad x(0) = x_0.$$

Let the time interval be h . Suppose that at time $(n-1)h$ we are at x_{n-1} . Then a good *predicted* value for x_{n+1} appears to be

$$\begin{aligned} p_{n+1} &= x_{n-1} + 2h x'_n \\ &= x_{n-1} + 2h X(x_n, t), \end{aligned}$$

since x'_n is the slope at the midpoint of the double interval. According to Hamming, the error term is $h^3 x'''(\theta)/3$.

The value p_{n+1} is now *corrected* by taking

$$c_{n+1} = x_n + h [x'_{n+1} + x'_n]/2,$$

where p_{n+1} is used to determine $p'_{n+1} = X(p_{n+1}, t)$. The error term for c_{n+1} is $-h^3 x'''(0)/12$. If x''' is approximately constant in the interval, then

$$\begin{aligned} p_{n+1} - c_{n+1} &= 5h^3 x'''/12 \\ &= (x_{n+1} - c_{n+1}) \cdot 5 \end{aligned}$$

or

$$\begin{aligned} x_{n+1} &= (4c_{n+1} + p_{n+1})/5 \\ &= [4x_n + p_{n+1} + 2h(x'_n + p'_{n+1})]/5, \end{aligned}$$

and

$$p'_{n+1} = X(p_{n+1}, \overline{n+1} h) .$$

To get started, we need x_1 in addition to x_0 . This is done by expanding in a Taylor's series

$$x_1 = x_0 + hx'_0 + h^2 x''_0/2 + \dots .$$

Hamming recommends carrying the series to the h^3 or h^4 terms. In our applications we have stopped frequently at h^2 because of the labor in computing x''_0 and x'''_0 . But note that if $h/2$ is used, the error is multiplied by $1/8$.

The preceding analysis is readily generalized to a system of four equations:

$$\begin{aligned} x' &= X(x, y, u, v, t) & y' &= Y(x, y, u, v, t) \\ u' &= U(x, y, u, v, t) & v' &= V(x, y, u, v, t) . \end{aligned}$$

We have

$$\begin{aligned} p_{n+1} &= x_{n-1} + 2hx'_n & q_{n+1} &= y_{n-1} + 2hy'_n \\ r_{n+1} &= u_{n-1} + 2hu'_n & s_{n+1} &= v_{n-1} + 2hv'_n \end{aligned}$$

$$p'_{n+1} = X(p_{n+1}, q_{n+1}, r_{n+1}, s_{n+1}, \overline{n+1} h) .$$

etc.

$$x_{n+1} = [4x_n + p_{n+1} + 2h(x'_n + p'_{n+1})]/5$$

etc.

20.4. PROGRAM NOTES

1. For each equation we need temporary storage for x_{n-1} , x_n , x'_n , p_{n+1} . Reference to the register contents on the first page of

the program listing shows how the storage is laid out. Secondary (protected) storage must of course be used. Fortunately, in indirect control the registers S0 to S9 become 10 to 19, so that $f P \leftrightarrow S$ switching of primary and secondary registers need not be programmed.

2. Label numbers are assigned to the subroutines that compute X, Y, U, V to agree with the register numbers where x_n, y_n, u_n, v_n are stored. That is, LBL 3 ~ 3, LBL 7 ~ 7, LBL B ~ 11, LBL A ~ 15 in the indirect control mode. Hence if we are working with the equation for V, say with 15 in the I-register, then $f GSB(i)$ sends us to the correct routine for the fourth equation of the set.

3. In evaluating the functions X, Y, U, V, the locations of x, y, u, v are assumed by the programming to be 3, 7, S1, S5. Hence in evaluating p'_{n+1} , etc., we must be careful to move x_n from 3 to 2, etc., and then p_{n+1} from 5 into 3, etc.

4. Extensive use of ISZ and DSZ is made to drive indirect control to the right addresses at the right time.

5. Time is incremented by $RCL \phi, STO + 1$.

6. To keep track of the number of equations in the set, store m, the number of equations, in both D and E initially. On each cycle, as an equation is processed, the value in D is decreased by 1. A test tells if all equations have been processed, that the iteration is complete, that time may be incremented, and D reset to m. That is, the program may be used for any number m of equations up to 4.

Example. The equations for the motion of a particular hydrostatic pendulum are $d^2x/dt^2 + 3 dy/dt + 4x = 0$, $d^2y/dt^2 - 3dx/dt + 4y = 0$, with $x_0 = 1$, $y_0 = 0$, $x'_0 = 0$, $y'_0 = 4$. You can almost smell--but not quite--that the exact solution is

$$x = \cos 4t \quad y = \sin 4t ,$$

which is indeed the case.

The equivalent system of four equations is

$$x' = u \quad y' = v \quad u' = -4x - 3v \quad v' = -4y + 3u .$$

The values for $t = h$ are readily found by expanding, using

$$\begin{array}{cccc} x_0 = 1 & y_0 = 0 & u_0 = 0 & v_0 = 4 \\ x'_0 = 0 & y'_0 = 4 & u'_0 = -16 & v'_0 = 0 \\ x''_0 = -16 & y''_0 = 0 & u''_0 = 0 & v''_0 = -64 \\ x'''_0 = 0 & y'''_0 = -64 & u'''_0 = 256 & v'''_0 = 0 \end{array}$$

to get

$$\begin{array}{ll} x_1 = 1 - 16h^2/2 & y_1 = 4h - 64h^3/6 \\ u_1 = -16h + 256h^3/6 & v_1 = 4 - 64h^2/2, \end{array}$$

which are recognized as the leading terms in the series for $\cos 4t$, $\sin 4t$, $-4 \sin 4t$, $4 \cos 4t$, respectively. For $h = 0.025$ we have, to 4 places,

$$x_1 = 0.9950 \quad y_1 = 0.0998 \quad u_1 = -0.3993 \quad v_1 = 3.9800,$$

but these values are stored in registers 3, 7, S1, S5 as they are computed to maintain full accuracy. (Remember $f P \leftrightarrow S$.) Also store the initial values in 2, 6, S0, S4, store $m = 4$ in D and E, and store $h = 0.025$ in 0 and 1. Now load the program.

Next program the functions by GTO.121, switch to W/PRGM, and then

```
f LBL 3, f P ↔ S, RCL 1, f P ↔ S, h RTN;
f LBL 7, f P ↔ S, RCL 5, f P ↔ S, h RTN;
f LBL B, RCL 3, 4, x, CHS, f P ↔ S, RCL 5, 3, x, -,
    f P ↔ S, h RTN;
g LBL a: RCL 7, 4, x, CHS, f P ↔ S, RCL 1, 3, x, +,
    f P ↔ S, h RTN .
```

Switch to RUN and press A. In the following tabulation we will record only x and y at intervals of $2h = 0.05$. The numbers beneath are the exact values, where we first shift to the radian mode by h RAD to get $\cos 4t$ and $\sin 4t$.

| <u>t</u> | <u>h = 0.025</u> | <u>h = 0.05</u> | <u>h = 0.025</u> | <u>h = 0.05</u> |
|----------|--------------------|-----------------|------------------|-----------------|
| | <u>x</u> | <u>x</u> | <u>y</u> | <u>y</u> |
| 0.05 | .9801 (.9801) | | .1986 (.1987) | |
| 0.10 | .9210 (.9211) | .9482 | .3894 (.3894) | .3158 |
| 0.15 | .8253 (.8253) | .8687 | .5646 (.5646) | .4938 |
| 0.20 | .6967 (.6967) | .7525 | .7173 (.7174) | .6573 |
| 0.25 | .5403 (.5403) | .6070 | .8414 (.8415) | .7935 |
| 0.30 | .3623 (.3624) | .4371 | .9319 (.9320) | .8981 |
| 0.35 | .1699 (.1700) | .2499 | .9853 (.9854) | .9670 |
| 0.40 | -.0292 (-.0292) | .0528 | .9994 (.9996) | .9972 |

For this example and with a spacing of $h = 0.025$, accuracy and absolute stability are excellent, although the running time is about 24 sec per iteration and 21 sec per display of the four variables. On the other hand, a spacing of $h = 0.05$ caricaturizes the solution. This points up the wisdom of doing a second run with half the original interval to determine whether major changes are occurring.

21. CURVE FAMILIES AND MACH NUMBERS

21.1. REFERENCES

21.2. DISCUSSION

Military data for analytic or operational use are frequently presented as a family of curves $z = f(x,y)$, where y is the parameter naming the family's members. For example, Fig. 21.1 (taken from Ref. a) is a nomogram to determine, for the A-7D aircraft, the Mach number to maximize range for constant altitude cruise, given average gross weight and drag index.* To use the nomogram, start with the average gross weight on the upper left scale. Move horizontally to the pressure altitude. Drop vertically to the appropriate drag index curve. Move horizontally to the left to read the true Mach number for long-range cruise. Page after page of such nomograms appear in the mission-planning appendix of Ref. a. Similarly, page after page of similar nomograms appear in Ref. b, to be used in planning space missions.

Neither Ref. a nor Ref. b gives the equations of the curve families. When these equations can be found, and if they are relatively simple, they can be readily programmed. Frequently, however, as in the case of an ephemeris or almanac that tabulates the coordinates of celestial bodies for astronomical and navigational use, the underlying equations are extremely complex. To quote from Ref. c, these

*The drag index is not a drag coefficient. Its determination, as explained in detail in Ref. a, is a tabulation of the drag contributions of external stores by type and station. The clean aircraft has a drag index of 0.

Fig. 21.1— Optimum Mach number

tabulations "should ideally be replaced by concise mathematical expressions for direct calculations. Such expressions must take the form of mathematical approximations, however, since the precise data . . . are calculated from extensive theories. . . ." Hence, the Observatory's Circular No. 155 provides the coefficients for the efficient expansion of tabulations in a series of Chebyshev polynomials. (These are *not* curve families, but functions of a single variable.)

In other cases, a curve family may arise from empirical observations such as flight tests, or may be the presentation of the results of extensive computer simulations.

In all cases, the question is: Can approximations be found for the family that are of *equivalent*^{*} accuracy to the data, and that are well within the capabilities of the HP-67 to implement?

Such approximations do not provide insight in respect to the physical nature of the underlying phenomenon or model if polynomial approximations are used. Polynomials are usually employed because of their simplicity and convenience. If, however, physical arguments or the methods of dimensional analysis suggest a functional relationship among the variables, this relationship should certainly be used in the approximation. More modestly, as we shall see shortly, it is always desirable to consider taking the logarithms of the dependent variable observables and then subjecting these values to a polynomial fit.

The obvious approach to finding a polynomial approximation for the set of observables (x_i, y_i, z_{ij}) is, in principle, by the method of least squares.^{**} For example, let

$$f(x,y) = a_0 + a_1x + a_2y + a_3x^2 + a_4xy + a_5y^2 \quad (1)$$

^{*} *Equivalent* means a calculated result within 1 percent or 2 percent of the result of reading directly from the curves. And one must keep in mind that (a) the width of plotted curves and the way in which they are drawn can introduce discrepancies of this order in the basic readings of values on which to base an approximation, and (b) the accuracy of the presented data is usually unknown.

^{**} In more modern guise, by orthonormalizing codes. See John Todd (ed.), *Survey of Numerical Analysis*, Chap. 10, McGraw-Hill, New York, 1962.

be the predictor. Then choose the coefficients a_1 to minimize

$$G = \sum_{i,j} [z_{ij} - f(x_i, y_j)]^2. \quad (2)$$

Take the six partial derivatives of G with respect to the coefficients and equate each to zero. Form the indicated sums and get six linear algebraic equations for the coefficients a_0, \dots, a_5 .^{*}

This is principle. In practice we have two problems:

1. Even this "best" approximation by a second-order polynomial may be of unacceptable accuracy.
2. No method in two dimensions is known that is equivalent to the use of Chebyshev polynomials in one-dimensional fitting which gives the "best" (most economical) fit for a polynomial of given order.

Frankly experimental methods are used to get an acceptable fit for the curve families encountered. As a working tool, the efficient Chebyshev approximation program available as Program 14 in the HP-67/HP-67 Stat Pac 1 is exploited. It is also advisable to stare hard and long at the graphs of the particular family to get ideas from the geometry (one version of the "low cunning" approach to ad hoc computing). Generalization to your problems of the methods employed in the examples below cannot be guaranteed.

21.3. TRUE MACH NUMBER

Staring at the upper set of straight-line segments in Fig. 21.1 gives the image that they might all originate as a sheaf from a common origin. Use of a straightedge shows that this surmise is at least approximately true. Hence, try as the functional form for the fit, the relation

^{**} A program for the solution of 6 equations in 6 unknowns is given in the HP-67/HP-97 Users Library Solutions book "High-Level Math," programmed by R. E. DeBolt.

$$x = m(H) \cdot G - 20 ,$$

where $m(H)$ is the slope for altitude H in kft, G is the average gross weight in klb, and x is the dummy variable for the nomogram. We now build the following table:

| (1) | (2) | (3) | (4) | (5) | (6) | (7) |
|-----|--------|----------|------------|----------|------------------------------|-----------|
| H | $m(H)$ | Δ | $\ln m(H)$ | Δ | $\frac{\exp}{(\text{quad})}$ | $a_0 = 0$ |
| 0 | 1.000 | | 0 | | 1.000 | 1.000 |
| | | 0.198 | | 0.1807 | | |
| 5 | 1.198 | | 0.1807 | | 1.196 | 1.196 |
| | | 0.251 | | 0.1902 | | |
| 10 | 1.449 | | 0.3709 | | 1.442 | 1.442 |
| | | 0.317 | | 0.1978 | | |
| 15 | 1.766 | | 0.5687 | | 1.752 | 1.753 |
| | | 0.348 | | 0.1799 | | |
| 20 | 2.114 | | 0.7486 | | 2.146 | 2.147 |
| | | 0.455 | | 0.1949 | | |
| 25 | 2.569 | | 0.9435 | | 2.649 | 2.649 |
| | | 0.772 | | 0.2628 | | |
| 30 | 3.341 | | 1.2063 | | 3.295 | 3.296 |
| | | 0.892 | | 0.2366 | | |
| 35 | 4.233 | | 1.4429 | | 4.130 | 4.131 |
| | | 1.086 | | 0.2220 | | |
| 40 | 5.309 | | 1.6649 | | 5.219 | 5.220 |
| | | 1.206 | | 0.2092 | | |
| 45 | 6.515 | | 1.8741 | | 6.645 | 6.646 |

Column (2) is obtained by reading differences from the figure and dividing. Considerable noise can be introduced by this process. (I used an 8X loupe. It is probably better to plot the values to a large scale and fair a curve through the points, and then read off values.) The increasing first differences of column (3) suggest that an exponential form be used since the exponent will be much flatter. This is shown by the differences of column (5).

A quadratic fit to $\ln m(H)$ should be good. We find from the HP-67 Stat Pac 1 program (six minutes to run) that

$$\ln m(H) = -2.04 \times 10^{-4} + 0.0351H + 1.56 \times 10^{-4} H^2 . \quad (3)$$

A comparison of columns (1) and (6) which is $\bar{m}(H)$ shows the adequacy of the fit. Column (7) shows that the constant term may safely be put equal to 0.

The lower family of curves in Fig. 21.1 requires a true two-dimensional fit. This family is well behaved in that a second-order polynomial fit looks promising (Eq. (1)). Moreover, try the fit with the coefficient a_4 of the cross term xy put equal to 0, because the curves are so nearly parallel. That is, $\partial f / \partial x = a_1 + 2a_3x + a_4y$ and the dependence on y is weak.

Proceed as follows.

1. Read from the curves the values of M at 35 points, using increments of 20 for x and 50 for y (the drag index). Do not use $y = 300$, reserving it for an extrapolation check.
2. Use the HP Stat Pac 1 Program 14 to get the following direct and cross-fits. (The second-order Chebyshev fit is used and the time per case is well under 10 min.)

$$\begin{aligned}
 f(x,0) &= 0.530 + 0.00500x - 1.8155 \times 10^{-5} x^2 \\
 f(x,50) &= 0.477 + 0.00527x - 2.054 \times 10^{-5} x^2 \\
 f(x,100) &= 0.430 + 0.00539x - 1.987 \times 10^{-5} x^2 \\
 f(x,150) &= 0.398 + 0.00571x - 2.232 \times 10^{-5} x^2 \\
 f(x,200) &= 0.378 + 0.00543x - 1.875 \times 10^{-5} x^2 \\
 f(0,y) &= 0.531 - 0.00122y + 2.286 \times 10^{-6} y^2 \\
 f(20,y) &= 0.611 - 0.00091y + 1.143 \times 10^{-6} y^2 \\
 f(40,y) &= 0.690 - 0.00085y + 1.143 \times 10^{-6} y^2 \\
 f(60,y) &= 0.771 - 0.00102y + 1.857 \times 10^{-6} y^2 \\
 f(80,y) &= 0.809 - 0.00090y + 1.571 \times 10^{-6} y^2
 \end{aligned}$$

3. The near constancy of the coefficients is promising. Using simply their means,

$$\begin{aligned}
 f(x,y) &= f(0,y) + 0.00536x - 1.993 \times 10^{-5} x^2 \\
 f(x,y) &= f(x,0) - 0.00098y + 1.600 \times 10^{-6} y^2 .
 \end{aligned}$$

From these

$$f(x,y) = f(0,0) + 0.00536x - 1.993 \times 10^{-5} x^2 \\ - 0.00098y + 1.600 \times 10^{-6} y^2 ,$$

where $f(0,0) = 0.53$.

4. Programming the last expression for $f(x,y)$ and checking its output against the 35 observed values yields a good fit. But using the HP improves one's "nose for numbers." There are some systematic biases in the fit. The dependence on x is somewhat strong, and the dependence on y can be weakened slightly. Adjusting to

$$f(x,y) = 0.53 + 0.0052x - 2 \times 10^{-5} x^2 - 0.001y + 1.5 \times 10^{-6} y^2 , \quad (4)$$

the mean absolute error with respect to the 35 observations is 0.0076 and the maximum error is 0.016.

5. It is now trivial to program Eqs. (3) and (4). The eight constants can be stored in primary registers 0 through 7 and recorded via f W/DATA on side two of the program card. Running time is three seconds. The output over the entire nomogram agrees to ± 0.01 .

22. TEN-POINT GAUSSIAN INTEGRATION

22.1. REFERENCE

- a. M. Abramowitz and I. A. Stegun (eds.), *Handbook of Mathematical Functions*, National Bureau of Standards Applied Mathematics Series 55, U.S. Department of Commerce, 3d Printing, March 1965.

22.2. DISCUSSION

This section gives a utility program to evaluate definite integrals with high accuracy. If the integrand becomes infinite at some point within the limits of integration, divide the integral into two parts, using as limits values slightly less and greater than that point. Accuracy is checked by varying these values and reevaluating. In fact, even if the integrand does not exhibit this behavior, accuracy can be checked by dividing the interval into two or more parts.

22.3. EQUATIONS

Gauss's formula for an arbitrary interval is (Ref. a, p. 887, 25.4.30):

$$\int_a^b f(y) dy \doteq \frac{b-a}{2} \sum_{i=0}^4 w_i \left\{ f\left(\frac{b-a}{2} x_i + \frac{b+a}{2}\right) + f\left(-\frac{b-a}{2} x_i + \frac{b+a}{2}\right) \right\}. \quad (1)$$

The abscissae x_i are the zeros of the Legendre orthogonal polynomial $P_5(x)$. The weights w_i are given by a formula involving $P'_5(x)$.

The values are

| | |
|---------------------|---------------------|
| $x_0 = 0.148874339$ | $w_0 = 0.295524225$ |
| $x_1 = 0.433395394$ | $w_1 = 0.269266719$ |
| $x_2 = 0.679409568$ | $w_2 = 0.219086363$ |
| $x_3 = 0.865063367$ | $w_3 = 0.149451349$ |
| $x_4 = 0.973906529$ | $w_4 = 0.066671344$ |

These are keyed into a data card with x_i stored in primary registers 0 to 4, and w_i in the secondary registers.

22.4. PROGRAM NOTES

The program is straightforward and has no features of interest.

PROBLEM

Write a program to evaluate elliptic integrals of the first kind:

$$F(\phi, \alpha) = \int_0^{\phi} (1 - \sin^2 \alpha \cdot \sin^2 \theta)^{-1/2} d\theta.$$

(1) Load data and program cards. The integral will be evaluated in the radian (h RAD) mode, but ϕ and α are usually given in degrees.

(2) STO 0 in A and ϕ in degrees in B.

STO α in degrees in E.

(3) GTO A and switch to W/PRGM. Key in the steps:

h RAD, RCL B, g \rightarrow R, STO B, RCL E, g \rightarrow R, f sin, g x^2 STO E.

(4) Switch to RUN, GTO E, switch to W/PRGM, and key in the steps:

f sin, g x^2 , RCL E, x, CHS, 1, +, f \sqrt{x} , h 1/x.

(5) Switch to RUN and press A. DSP 8.

$\phi = 30^\circ$, $\alpha = 40^\circ$, $F(30, 40) = 0.533\ 427\ 45$

$\phi = 65^\circ$, $\alpha = 60^\circ$, $F(65, 60) = 1.348\ 926\ 43$.

These agree exactly with the tabular entries (Table 17.5) of Ref. a.
Running time is about 30 sec.

22.5 USER INSTRUCTIONS

22. TEN POINT GAUSSIAN INTEGRATION

23.2. DISCUSSION

This section describes a calculus of propositions based on a binary algebra for logical connections and operations particularly suited for calculator implementation as well as easy algebraic manipulation.

Letters of the alphabet will stand for propositions. To illustrate, choosing propositions to be used in an example to follow, let

- a stand for "A man is a mathematician."
- b stand for "A man likes whisky at night."
- c stand for "A man likes Mozart in the morning."
- d stand for "A man waits 20 minutes for a bus."

In the two-valued calculus, a proposition has a truth value of 0 (false) or 1 (true), $a = 0$ or $a = 1$. For example, writing $a = 1$ means "A man is a mathematician."

Propositions may be operated on or connected by logical operations. A truth table corresponds to each such operation. Ordinary language

will be used instead of special symbols. For each basic logical operation, a truth table shows the truth value of the operation for all combinations of truth values of its component propositions. Such basic truth tables can be summarized in binary algebraic form. This is verified in the right-hand column of the tabulation below.

| Operation | | Truth Table | | | | Binary Algebraic Form |
|--|----------------------------|-------------|-------------|-------------|-------------|-----------------------|
| NOT a | a NOT a | 0 1 | 1 0 | | | $1 - a$ |
| a AND b | a b a AND b | 0 0 0 | 1 0 0 | 0 1 0 | 1 1 1 | ab |
| a AND/OR b | a b a AND/OR b | 0 0 0 | 1 0 1 | 0 1 1 | 1 1 1 | $a + b - ab$ |
| a OR ELSE b | a b a OR ELSE b | 0 0 0 | 1 0 1 | 0 1 1 | 1 1 0 | $a + b - 2ab$ |
| IF a THEN b | a b IF a THEN b | 0 0 1 | 1 0 0 | 0 1 1 | 1 1 1 | $1 - a + ab$ |
| (Note that a false proposition can imply either truth or falseness. Also observe that 'NOT (IF a THEN b)' is 'a AND NOT b'.) | | | | | | |
| NOT BOTH a AND b | a b NOT BOTH a AND b | 0 0 1 | 1 0 1 | 0 1 1 | 1 1 0 | $1 - ab$ |
| (This is the negation of AND.) | | | | | | |
| NEITHER a NOR b | a b NEITHER a NOR b | 0 0 1 | 1 0 0 | 0 1 0 | 1 1 0 | $1 - a - b + ab$ |
| (This is the negation of AND/OR.) | | | | | | |
| a LIKE b | a b a LIKE b | 0 0 1 | 1 0 0 | 0 1 0 | 1 1 1 | $1 - a - b + 2ab$ |
| (This is equivalence and is the negation of OR ELSE.) | | | | | | |

Binary algebra has some interesting features not found in ordinary algebra. Since the variables can take on only the values 0 and 1, $a^2 = a$ and $ab(1 - a + ab) = ab - ab + ab = ab$, which is readily checked by the truth table:

| | | | | |
|------------------|---|---|---|---|
| a | 0 | 1 | 0 | 1 |
| b | 0 | 0 | 1 | 1 |
| ab | 0 | 0 | 0 | 1 |
| $1 - a + ab$ | 1 | 0 | 1 | 1 |
| $ab(1 - a + ab)$ | 0 | 0 | 0 | 1 |

On the other hand, a proposition appearing on both sides of an = sign cannot be cancelled, because this could be division by 0.

The use and manipulation of these binary algebraic functions can be illustrated by a problem that Walter Pitts of the Massachusetts Institute of Technology set long ago on an examination (Ref. a).

Suppose 1 through 4 below are known to be true:

1. If a mathematician does not have to wait 20 minutes for a bus, then he either likes Mozart in the morning or whisky at night, but not both.

2. If a man likes whisky at night, then he either likes Mozart in the morning and does not have to wait 20 minutes for a bus or he does not like Mozart in the morning and has to wait 20 minutes for a bus or else he is no mathematician.

3. If a man likes Mozart in the morning and does not have to wait 20 minutes for a bus, then he likes whisky at night.

4. If a mathematician likes Mozart in the morning, he either likes whisky at night or has to wait 20 minutes for a bus; conversely, if he likes whisky at night and has to wait 20 minutes for a bus, he is a mathematician--if he likes Mozart in the morning.

Then:

When does a mathematician wait 20 minutes for a bus?

To solve this problem, first translate each condition from English to the language of propositions and logical connectives,* and then express the result in binary algebra. Because each of the four above conditions is true, each algebraic expression is put equal to 1 and then simplified.

1. IF(a AND NOT d) THEN(b OR ELSE c).

$$\begin{aligned} 1 - a(1 - d) + a(1 - d)(b + c - 2bc) &= 1, \\ a(1 - d)(b + c - 2bc - 1) &= 0. \end{aligned} \quad (1)$$

2. IF b THEN(((c AND NOT d) OR ELSE(NOT c AND d))
OR ELSE(NOT a)).

To simplify, set $A = (c \text{ AND NOT } d) \text{ OR ELSE}(\text{NOT } c \text{ AND } d)$.
Then $A = c(1 - d) + d(1 - c) - 2cd(1 - c)(1 - d)$
 $= c + d - 2cd$.

That is, the proposition A is equivalent to the proposition "c OR ELSE d". Making this substitution, we obtain

$$\begin{aligned} 1 - b + b(c + d - 2cd + 1 - a) \\ - 2(1 - a)(c + d - 2cd) &= 1, \\ b(-a + (c + d - 2cd)(2a - 1)) &= 0. \end{aligned} \quad (2)$$

3. IF(c AND NOT d) THEN b.

$$\begin{aligned} 1 - c(1 - d) + cb(1 - d) &= 1, \\ c(1 - d)(1 - b) &= 0. \end{aligned} \quad (3)$$

- 4a. IF(a AND c) THEN(b OR ELSE d).

$$\begin{aligned} 1 - ac + ac(b + d - 2bd) &= 1, \\ ac(b + d - 2bd - 1) &= 0. \end{aligned} \quad (4)$$

*Ref. e is helpful in this respect.

4b. IF c THEN(IF (b AND d) THEN a).

$$1 - c + c(1 - bd + abd) = 1 ,$$

$$bcd(1 - a) = 0 . \quad (5)$$

To answer the question, put $a = 1$ and $d = 1$ in (1) through (5), since these two propositions must be true. The interpretation of the question is delicate. The question is rephrased here as: What values of b and c are associated with $a = 1$ and $d = 1$ to make all conditions of the problem true? The set of conditions reduces to

$$bc = 0 .$$

This means NOT BOTH b AND c (that is, $1 - bc = 1$), which may be expressed

- A. When he likes neither Mozart in the morning nor whisky at night.
- B. When he likes whisky at night and not Mozart in the morning.
- C. When he likes Mozart in the morning and not whisky at night.*

Of course, many questions other than the one above could be asked. To be exhaustive, this means: Find all values for the set of propositions (a,b,c,d) that satisfy all given conditions. The program of this section is designed to examine systematically all cases, here 16 in number. Programming the conditions and running the program yields only eight satisfactory combinations of (a,b,c,d) .

| | <u>a</u> | <u>b</u> | <u>c</u> | <u>d</u> |
|---|----------|----------|----------|----------|
| | 0 | 0 | 0 | 0 |
| | 0 | 1 | 0 | 0 |
| | 0 | 0 | 1 | 0 |
| | 0 | 0 | 0 | 1 |
| → | 1 | 0 | 0 | 1 |
| → | 1 | 1 | 0 | 1 |
| | 0 | 0 | 1 | 1 |
| → | 1 | 0 | 1 | 1 . |

* Something of a furor erupted in the Letters section of the *Scientific American* of February 1951 because Pfeiffer had not given an answer in his article. Pfeiffer and Morris gave the first part of C as the answer. Krause gave the first part of B, and Bomgren gave answer A.

This is the truth table method. The lines indicated by arrows are the answers to the given problem.

The logical structure of the problem may also be captured by using the truth table to construct a Venn diagram.

Suppose a point placed on this page represents a man. Group together all men who are mathematicians so that this subset is enclosed:

then all inside men have the value $a = 1$, those outside the value $a = 0$.

From the truth table, whenever $a = 1$, $d = 1$. But there are cases where $a = 0$ and $d = 1$. Hence the set a is properly contained in the set d . Logically this means "if a then d ", and algebraically " $a = ad$ ". Similarly, c is contained in d . But for a and c , by the last four lines of the truth table, there are the combinations 10, 01, 11. Hence a and c have points in common--they intersect.

Turning to the set b , since $bc = 0$ in all cases, the sets b and c are disjoint--they do not intersect. But b intersects a and also intersects d . However, because of the line 1101, and because there is no line 0101, these latter two intersections are the same subset.

Putting all of this together yields the following diagram:

Returning to the original algebraic formulation, it is readily seen that all conditions are satisfied by appeal to this diagram. For example, since $bc = 0$ and $abd = ab$, in (2) above $ab = bd$.

The original question asked by this problem is not clear. It would be better to ask, *What can be said about a mathematician?*

The answer to this question is:

- He always waits 20 minutes for a bus;
- He does not like both whisky at night and Mozart in the morning, although he may like one or the other.

The calculus of propositions, a branch of symbolic logic, has found applications in optimizing switching circuit design, in determining insurance eligibility (an example from Ref. b will be given in the next section), in deciding on plant location (Ref. d), and in the interpretation of contracts and law. Walter Cushen, in a fascinating chapter in Ref. c, discusses applications to production engineering and to conflicts formulated as multi-move games.

23.3. EQUATIONS

None.

23.4. PROGRAM NOTES

Since the program flow is somewhat complex, a flowchart is provided.

Suppose there are n propositions. Then there are 2^n cases to examine, which are actually numbered $0, 1, \dots, 2^n - 1$. Each case number in its turn is reduced to its binary form, but stored backwards in R_1 to R_n . Indirect addressing is used.

Each condition is examined in turn, the examination halting at the first condition that is not satisfied. If all conditions are satisfied, the binary case number is displayed. R/S continues to the next valid case. The end is signalled by the decimal display of $2^n - 1$.

As programmed, there is space for 7 propositions. If a problem requires more than 7, make some slight programming changes. Primary

registers 8 and 9 are shifted to secondary 8 and 9. Then up to 18 propositions can in principle be handled. For large problems, however, there is apt to be a large number of conditions and there may not be adequate space available to program them. Moreover, execution time will be long. It is wise to do as much algebraic manipulation on the set of conditions as is feasible to simplify the set.

In problems where some propositions are held constant, the constant value(s) (0 or 1) are stored manually in some register(s) above R_n , but only if these are needed in programming the conditions.

EXAMPLE

This is a group insurance problem taken from Ref. b (pp. 161-165). The rules (conditions) applying to employees are:

1. Any employee, to be insured, must be eligible for insurance, must make application for insurance, and must have such application for insurance approved.
2. Only eligible employees may apply for insurance.
3. The application of any person eligible for insurance without medical examination is automatically approved.
4. (Naturally) an application can be approved only if the application is made.
5. (Naturally) a medical examination will not be required from any person not eligible for insurance.

The propositions are 5 questions about an employee to be answered "yes" (1) or "no" (0). These are:

- a: Is the employee eligible for insurance?
- b: Has the employee applied for insurance?
- c: Has the employee's application for insurance been approved?
- d: Does the employee require a medical examination for insurance?
- e: Is the employee insured?

The conditions are translated:

1. IF e THEN(a AND b AND c)

$$e(1 - abc) = 0 .$$

2. IF b THEN a

$$b(1 - a) = 0 .$$

3. IF a AND b AND NOT d THEN c

$$ab(1 - d)(1 - c) = 0 .$$

4. IF c THEN b

$$c(1 - b) = 0 .$$

5. IF NOT a THEN NOT d

$$d(1 - a) = 0 .$$

The question is "What are the possible statuses of employees who are not insured?" This means that e must be put equal to 0. But then the first condition is irrelevant since a false proposition implies any proposition.

SOLUTION

Load program. Key GTO B. Switch to W/PRGM. Now key in the condition in the order 2, 4, 5, 3. That is, the simplest conditions are entered first to save execution time. The program steps are:

| | | | | | | | | |
|-----|---------|-----|---------|-----|---------|-----|-------|-------|
| 072 | 1 | 079 | 1 | 086 | 1 | 093 | 1 | RCL 1 |
| | RCL 1 | | RCL 2 | | RCL 1 | | RCL 4 | x |
| | - | | - | | - | | - | RCL 2 |
| | RCL 2 | | RCL 3 | | RCL 4 | | 1 | x |
| | x | | x | | x | | RCL 3 | h RTN |
| | f x ≠ 0 | | f x ≠ 0 | | f x ≠ 0 | | - | |
| | h RTN | | h RTN | | h RTN | | x . | |

(Note that if conditions 2 to 5 were multiplied,

$$abcd(1 - a)(1 - b)(1 - c)(1 - d) = 0 ,$$

which is true for *all* cases. The multiplication has destroyed the meaning of the individual conditions by absorption.)

Now switch to RUN. Key 4 (the number of propositions) and Press A. See 0. This is actually the status 0000 for a,b,c,d. On successive presses of R/S you will see 1000, 1110, 1001, 1101, 1111, 15 (the number of cases minus 1).

Using the definitions of a,b,c,d, these 5 statuses rapidly translate into an answer to the question.
